AMERICAN JOURNAL OF PSYCHIATRY

INFORMATION FOR CONTRIBUTORS

Manuscripts—The *original* manuscripts of papers read at the annual meetings of the Association should be deposited with the Secretary during the meetings, or sent to the New York office promptly afterward. Do not deposit carbon copies.

Papers read at the annual meetings become the property of the Association. Not all papers read, however, can be published in the JOURNAL, and authors wishing to publish in other vehicles will first secure from the Editor the release of their manuscripts.

Papers will not be accepted for the annual program if they have been previously read at other meetings or if they have been already published.

Papers contributed during the year (not on the annual program) should be sent to the Editor, Dr. Clarence B. Farrar, 216 St. Clair Avenue, West, Toronto 7, Ontario, Canada.

Style—Manuscripts should be typewritten, double spaced, on one side of the paper. They must be prepared in conformity with the general style of The American Journal of Psychiatry. Retain a carbon copy of manuscript and duplicates of tables, figures, etc., for use should the originals be lost in the mails.

Multiple Authorship—The number of names listed as authors should be kept to a minimum, others collaborating being shown in a footnote.

Illustrations—Authors will be asked to meet printer's costs of reproducing illustrative material. Copy for illustrations cannot be accepted unless properly prepared for reproductions. Wherever possible, drawings and charts should be made with India ink for photographic reproduction as zinc etchings. Photographs for halftone reproduction should be glossy prints. Illustrations should be as small as possible without sacrificing important detail. Redrawing or preparing illustrations to make them suitable for photographic reproduction will be charged to author.

Authors' Corrections in Proofs—Corrections, additions or deletions made by authors are to be charged to them. These alterations are charged on a time basis at the rate of \$7.00 per hour. Proper editing of original manuscript is important to avoid the expense of correction.

Tables—Tables should be typed on separate sheets. Tables are much more expensive to set than text material and should be used only where necessary to clarify important points. Authors will be asked to defray cost of excessive tabular material.

References—References should be assembled according to author in a terminal bibliography, referred to in text by numbers in parentheses. Bibliographical material should be typed in accordance with the following style for journals and books respectively:

1. Vander Veer, A. H., and Reese, H. H.: *Am. J. Psychiat.*, 95 : 271, Sept. 1938.
2. Hess, W. R.: *Diencephalon*. New York: Grune & Stratton, 1954.

Abbreviations should conform to the style used in the Quarterly Cumulative Index Medicus.

The American Journal of Psychiatry, formerly The American Journal of Insanity, the official organ of The American Psychiatric Association, was founded in 1844. It is published monthly, the volumes beginning with the July number.

Articles appearing in this Journal do not necessarily reflect the official attitude of The American Psychiatric Association or of the Editorial Board.

The subscription rates are \$12.00 to the volume: Canadian subscriptions \$12.50; foreign subscriptions, \$13.00, including postage. Rates to medical students, junior and senior internes, residents in training during their first, second, or third training year, and also to graduate students in psychology, psychiatric social work, and psychiatric nursing, \$5.00 (Canada \$5.50). Single issues, \$1.25. Copyright 1960 by The American Psychiatric Association.

Office of Publication, 10 Allen St., P.O. Box 832, Hanover, N. H.

Business communications, remittances and subscriptions should be addressed to The American Psychiatric Association, 10 Allen St., P.O. Box 832, Hanover, N. H., or to 1270 Avenue of the Americas, New York 20, N. Y.

Editorial communications, books for review, and exchanges should be addressed to the Editor, Dr. Clarence B. Farrar, 216 St. Clair Avenue, West, Toronto 7, Ontario, Canada.

Second class postage paid at Hanover, New Hampshire.

CONTENTS OF VOLUME 116

JULY, 1959

PRESIDENTIAL ADDRESS. <i>Francis J. Gerty</i>	1	A Study of the Value of the Funkenstein Test as an Indicator of the Effectiveness of the Ataractic Drugs. <i>Manfred Braun, and Seymour Rettek</i>	66
FRANCIS J. GERTY, M.D., EIGHTY-FIFTH PRESIDENT, 1958-1959: A BIOGRAPHICAL SKETCH. <i>Francis J. Braceland</i>	11	Treatment of Affective Depression With Trans-DL-Phenylcyclopropylamine Hydrochloride: A Preliminary Report. <i>Magnus C. Petersen, and John W. McBrayer</i>	67
HUNGARIAN REFUGEES: LIFE EXPERIENCES AND FEATURES INFLUENCING PARTICIPATION IN THE REVOLUTION AND SUBSEQUENT FLIGHT. <i>Lawrence E. Hinkle, Jr., Francis D. Kane, William N. Christenson, and Harold G. Wolff</i>	16	The Use of Triflupromazine With Iproniazid for the Treatment of Chronic Schizophrenic Patients. <i>Roger F. Reinhardt, Samuel B. Schiff, and E. Robert Sinnott</i>	68
THE SALIVARY CURVE: A PSYCHIATRIC THERMOMETER? <i>George F. Sutherland</i>	20	Clinical and Statistical Evaluation of Results With Plegicil AY-57062 in Chronic Mental Patients. <i>E. J. Tolan, J. Olarin, J. M. Rees, and H. A. Peppel</i>	69
LONGITUDINAL OBSERVATIONS OF BIOLOGICAL DEVIATIONS IN A SCHIZOPHRENIC INFANT. <i>Barbara Fish</i>	25	Clinical Results With Phenelzine. <i>John C. Saunders, Richard W. Roukema, Nathan S. Kline, and Samuel D'A. Bailey</i>	71
LEPROSY AND PSYCHOSIS. <i>Paul Lowinger</i>	32	HISTORICAL NOTES: A Note on Pliny Earle and Edgar Allan Poe. <i>Jerome M. Schneek</i>	73
SOME PSYCHOANALYTIC IDEAS APPLIED TO ELATION AND DEPRESSION. <i>Bertram D. Lewin</i>	38	ADMINISTRATIVE NOTES: Experiences in the Conversion of a Closed to an Open Psychiatric Ward in a General Hospital. <i>Kisik Kim, and Merrill T. Eaton, Jr.</i>	74
THERAPEUTIC FACTORS IN ALCOHOLICS ANONYMOUS. <i>Herbert S. Ripley, and Joan K. Jackson</i>	44	COMMENT: Philadelphia Meeting Highlights	77
CEREBRAL LOCALIZATION: NOT WHERE BUT IN WHOM? <i>Curtis Pechtel, and Jules H. Masserman</i>	51	Health Insurance for Psychiatric Patients.	79
UNDERGRADUATE PSYCHIATRIC EDUCATION AS REFLECTED IN FINAL EXAMINATIONS. <i>Charles Watkins, and Edward Knight</i>	55	CORRESPONDENCE: Role of Psychiatrists in Criminal Trials	80
EMOTIONAL CONTENT OF SUICIDE NOTES. <i>Jacob Tuckman, Robert J. Kleiner, and Mariba Lavell</i>	59	A Comment on "Swedish Psychiatry"	83
CLINICAL NOTES: Phenelzine and ECT in the Treatment of Depressions. <i>Peter D. King</i>	64	NEWS AND NOTES	85
The Phrenotropic Action of Trilafon (Perphenazine) in 323 Neuropsychiatric Patients. <i>Veronica N. Pennington</i>	65	BOOK REVIEWS	88
		IN MEMORIAM: Hans W. Gruhle, 1880-1958	95

AUGUST, 1959

SOURCES OF UNCERTAINTY IN STUDIES OF DRUGS AFFECTING MOOD, MENTATION OR ACTIVITY. <i>Erwin L. Linn</i>	97	IN A MENTAL HOSPITAL. <i>Benjamin Pasamanick, Simon Dinits, and Mark Lefston</i>	127
DIFFICULTIES OF COMPARATIVE PSYCHIATRY: THE FIJI ISLANDS. <i>Eric Berne</i>	104	AGGRESSION, GUILT AND CATAPLEXY. <i>Max Levin</i>	133
SEVEN YEARS OF AWAKENING: 1906-13. <i>Earl D. Bond</i>	110	THE PHYSIOLOGICAL BASIS OF THE TREATMENT OF DELIRIUM TREMENS. <i>Henry Krystal</i>	137
RHYTHMS, CYCLES AND PERIODS IN HEALTH AND DISEASE. <i>Franklin S. DuBois</i>	114	ALCOHOL IN THE IROQUOIS DREAM QUEST. <i>Edmund S. Carpenter</i>	148
THE CHALLENGE OF RESULTS IN PSYCHOTHERAPY. <i>Ian Stevenson</i>	120	A STATISTICAL STUDY OF FIRST ADMISSIONS WITH PSYCHONEUROSES IN NEW YORK STATE, 1949-1951. <i>Benjamin Malzberg</i>	152
RELATIONSHIPS AMONG SEIZURES, PSYCHOSIS AND PERSONALITY FACTORS. <i>Edwin A. Weinstein</i>	124	VALUE AND LIMITATIONS OF A PSYCHIATRIC DEPARTMENT IN A GENERAL HOSPITAL IN BOMBAY (INDIA). <i>N. S. Vabia</i>	158

CLINICAL NOTES :

- Clinical Evaluation of Trimeglamide in Anxiety. *Robert A. Braun, and Paul Lowinger* 163
- Potentiation and Facilitation of Insulin Coma Therapy. *J. B. Hayes, and Robert E. Kennedy* 164
- Clinical Results with the Use of Deanol (Deaner®) in Schizophrenia. *Veronica M. Pennington* 165
- A New Screening Test For Bromide Intoxication. *George H. Reye, and Joy R. Joffe* 166
- Promazine and Combined Promazine-Meprobamate Treatment of Hospitalized Psychotic Patients. *George Vlavianos, and Ludwig Fink* 168
- Drug Use-Rate in a State Hospital. *J. R. Whittier, C. D. Korenyi, O. Diamond, P. J. Tomlinson, and H. A. LaBurt* 169

ADMINISTRATIVE NOTES :

Mentally Disturbed Children on Wards with

- Adult Mental Patients. *On B. McAtee and George A. Zirkle* 172

COMMENT :

- Personality and Performance 173

CORRESPONDENCE :

- Concerning the Origin of the Terms Group Therapy and Group Psychotherapy 176
- Maladie Des Tics* in Children 177
- Electroshock Complication 179

Francis J. Gerty

PRESIDENTIAL ADDRESS

THE PHYSICIAN AND PSYCHOTHERAPY¹

FRANCIS J. GERTY, M.D.

God permitting and by your election I have served as your President during the past year. Of the honor of the election I am sharply aware and highly proud. During the year the bearing of the not inconsiderable weight of the burdens that go with serving in your highest office has yielded me great satisfaction. It is the satisfaction of knowing that the majority of you had the faith, the hope or the charity to believe I would bear such burdens at least passably well. Today you accord me a most special privilege,—that of saying publicly what I will on any matters related to our common work under your great trust that what I may say, even though an expression of my private opinions, will do our Association no discredit. I am humbly grateful for the privilege you grant me and the trust you repose in me.

In its content an address made at the ending of a term of office seems to divide quite naturally into two parts. One part concerns comments and projections of thought upon the events and developments experienced during the period of service.

The other and, to me, more pressing part of my privileged duty today, concerns a reexamination and discussion of some most important ways in which human relationships are involved in connection with the enduring principles upon which the practice of medicine was founded. The particular principles I will hold in view are these :—first, the physician should have a sufficient comprehension of what is required if he would treat the patient adequately as well as the diagnosable ills from which the patient may suffer; second, that while practically it may be necessary, often, to depend upon empirical remedies and also upon intuitive perception and procedure

in the relation of the physician to the patient, there should never develop a blind dependence upon these means, but rather the constant endeavor should be to subject empirical and intuitive means of treatment to as close scientific scrutiny as possible to find out the secrets of their operation. The condition of our knowledge establishes empiricism in the practice of our art. The requirement of science is that the condition of our knowledge should be improved to the end that in the practice of our art we will progressively need to ask less and less of empiricism and intuition. After I finish my review and comment upon our organizational happenings of the past year, my discussion of this subject will proceed on the theme of the physician and psychotherapy.

Some events worthy of notice now have happened during the past year. The outstanding ones are the first appearance of vice-presidents in the roster of our officers in the persons of Doctors William Terhune and David Wilson; the retirement of Doctor Daniel Blain as Medical Director and the assumption of that office by Doctor Mathew Ross; and finally, the occupation of the new home of the Association, the first which it has owned in the 115 years of its history. I have called upon both vice-presidents when I could for a readily proffered aid. Unfortunately, their duties have been poorly defined so far. Very particular service to the association amply justified their election to office. Doctor Terhune put together the foundation for our new home,—that is, he conducted the campaign for the dollar foundation, without which there would have been no home. Doctor Wilson has done much to build the foundation for a new part of our organization,—the Assembly of the District Branches, which more and more is shaping the ends of our work. I told Doctor Blain

¹ Presidential Address delivered at the 115th annual meeting of The American Psychiatric Association, Philadelphia, Pa., April 27-May 1, 1959.

that I wished he had picked some other time than my term of office to resign, so much do I, as I am sure do all of you, value the extraordinary worth of what our first medical director has done to develop American psychiatry through his position in The American Psychiatric Association. The search for a new medical director was a long one which Doctor Malamud and Doctor Branch pursued with assiduity and to good purpose for it has brought us Doctor Mathew Ross, who has glided into the stream of our activity smoothly and with firm stroke. As to the new home, I need say little except that you should visit it and discover that large though it may have seemed at first, already its busy staff finds no excess of room.

Our increasing membership is a reflection of a general public need—it is not an accident—nor is it purely an indication of our activities in improving treatment services in our specialty. So far we do not succeed in meeting the need fully. No specialty of medicine is or should be more sensitive in responding to this need,—a need arising in individuals and in the relationships of individuals to one another,—than ours.

The membership increase brings special organizational problems. We must be careful that organization does not become our most important business. Our chief attention must always be given to the improvement in our ability to do our primary work through every means that we can use to promote the increase of knowledge and to make that increase show as a value in application. Scientific discovery and education of others in the mysteries of our art and science are the things for which the chief prizes of recognition should be reserved. In small scientific organizations, election to office is a principal form of recognition. When the organization becomes large, the proneness to use the democratic process for all purposes often interposes a difficulty in the way of according recognition for scientific contribution through election to office. I would suggest that the Presidency might well be given sometimes, and not too infrequently, as a recognition to our leaders in the fields of thought and scientific exploration. Even this will not fully serve the purposes of

according recognition that should be given for research, for teaching, and for directing organization specifically to such purposes. Some of our members have deserved such recognition while they were living. The processes for granting it are still not well established. To some our recognition has come only posthumously and unofficially. One of our past presidents, Doctor Brace-land, has suggested that we officially establish some means of honoring those who furnish the chief sustenance for our growth. I join him in expressing the hope that this will be done. Organization for organization's sake will never suit the real ends and aims of medicine.

I have said that the growth of our association is an index of a public need. It is a need which is increasing. I shall not picture it in detail. Its bulky outlines must already loom before you. The country is moving into a period of great population growth. It is estimated that the present 179 million people in the United States will be 228 million by 1975, a little more than 15 years hence. Medical schools are graduating a few over 6,800 physicians a year currently (the figure for 1955-56 was 6,802). The projected plans do not indicate a very remarkable increase in this number since it is estimated that 8,000 will be graduated in 1970-71. For psychiatric treatment this deficiency of service is reflected very sadly in all states. The facts are so well known that I do not intend to restate them. I believe that the assumption of deficiency of psychiatric service is well enough justified that I may now turn to my theme of the physician and psychotherapy.

From its very beginning, even before history made the record, the practitioners of medicine have had to depend heavily on their understanding of human relationships and of the processes of thought and emotion existing within individual patients. Intuitive though that understanding may have been and empirical in its application, it has been one of the important instrumentalities of treatment. *In other words, something that constitutes the crude ore of psychotherapy has always been in use.* Like some of the rarer elements now becoming known in physics and chemistry and being put to use in terms of their scientifically known characteristics, the

refined elements of psychotherapy are being discovered and used. It will be my intention to point out that medicine must become aware of this,—much more aware of it than it seems to be at present and that it must be prepared to meet the enormous demand which is bound to occur in view of the statistical projections which I have indicated above. It is already obvious that in numerical production of physicians we shall be woefully inadequate. This makes the adequacy of preparation in view of present and impending demands all the more important. What can we say as to this preparation at the pre-medical level, at the pre-clinical level, and at the clinical level?

Speaking for the moment only of preparation for medical practice in a general way, not insofar as specialization is concerned, is a progressive and enlightened basic preparation for the refined uses of psychotherapy being given? Are those physicians at present in practice, many of whom are engaged in the teaching of the coming generation of physicians, aware of the needs for psychotherapy and its practical uses in the field of medical service? I do not intend to labor the point, but my impression is that there is still a greater proportional preoccupation with physical techniques and the application of physical means of treatment by them than there should be in view of the total picture as to need and effectiveness of remedy. Also in medicine a somewhat peculiar goal-setting tends to deviate teaching in general away from the goal of inculcating the best principles and practice of psychotherapy. This refers to intelligent recognition of the need for it, of its relation to other treatment, and of its use at least at the minimum level in every field of medical practice and at its optimum level in many instances. In this connection, I shall have to make some other observations. One concerns the remarkable development of specialization and sub-specialization in medicine. Here I return to goal setting.

We know that pre-medical education is particularly aimed at getting the student admitted to medical college. This may possibly be, and I believe it is, often at the sacrifice of giving him the preparation which he needs, and particularly that preparation which he will require if, in his later

practice, he is going to use the resources of psychotherapy judiciously and adequately. If the emphasis on having good grades in the physical basic sciences has this effect in setting the very first of the goals, what happens from then on? Is the nature of the medical curriculum and the characteristics and proclivities of the teachers such that there will be supplementation for what has been left out in the haste to reach the primary goal—the admission to the medical college? I doubt that medical curriculums are designed very adequately for this purpose. What, then, is the next goal which is set? My experience with medical students would indicate that it is the goal of specialization.

It is true that a considerable number of medical students still go into general practice. However, medical students are becoming aware that the general practitioner is now a somewhat handicapped member of the profession. His handicap is evident to him when he seeks appointment to a hospital staff, when he contemplates how much the illnesses which affect any human individual are divided up and parcelled out to practitioners of various specialties and sub-specialties who know their own field and its techniques extraordinarily well but who almost make a virtue of eschewing knowledge of things outside their own area of special competence. It is this which lays medicine, and not medicine alone, but the other learned professions open to the charge that they breed modern barbarians—persons not entirely ignorant because they know something very well, intelligent in a highly restrictive and technically selective way, so that one philosopher (Ortega y Gasset) has referred to them, including physicians, too, as intelligent ignoramuses. This is, of course, one of the difficulties of setting the goals to too special and utilitarian ends; of not setting them to the selection of thoughtful men who will use the broad base of knowledge for the purposes which will serve the best overall advantage of the patient.

It is my thought that the specialty of psychiatry is the broadest of all specialties in the setting of goals. In this respect it should contribute something of essential value in meeting an essential need. However, this will not be accomplished easily.

Though one must acknowledge the importance of psychotherapy in medical practice, from the very beginning the most ancient of all the ingredients in the physician's prescription for the patient because it includes the physician himself, one must also acknowledge that its teaching and gaining acceptance for its enlightened use is no easy matter. The obstacles are many and there is grave danger that medicine may lose its prerogative and privilege as to the use of psychotherapy unless there is some change in belief, in attitude, in teaching, and in practice within the fold of medicine. Some of these obstacles have been mentioned, including the preoccupation with special technical and practical goals and the lack of broad vision in planning the curriculums and programs of studies in our medical schools. Other obstacles are the specialist and sub-specialist character of psychiatry as it is commonly known to physician and layman alike. As psychotherapy in its modern form is a product of psychiatry, this becomes an obstacle to its widespread acceptance and use.

It would be very unwise to represent psychotherapy as a thing easy to define, easy to understand in theory and practice, and therefore easy to learn and apply. We realize well that it is quite the contrary in fact. However, the same observations may be made justly about the difficulties in the way of full understanding of the scientific basis for the use of whole categories of physical treatment. Even with reference to relatively simple drugs, such as opium or aspirin, easy to identify, measure, and administer, we know much more about what they do than about why and how they do it. The applications of knowledge drawn from the sciences as they are used in a profession and practical art such as medicine must always allow for a considerable measure of empiricism. This does not mean that no scientific basis will ever be found for what works in practice. Because something works or because we reason that it ought to work and find it doesn't should be a mandate to try to find out why. This applies to psychotherapy. It is well to remember this as a support to one's morale when a medical colleague, at some meeting or, worse still, in the ward of a hospital or at a clinical conference with

students, indicates with some expression of bland and quiet agnosticism that the foundation for most formally practiced psychotherapy is an imagined structure, certainly not a truly scientific one. Such a critic may use certain therapeutic devices quite regularly in his own treatment of patients which we would have to classify as fitting into the general category of psychotherapy,—such things as reassurance, persuasion, suggestion, or most commonly an individually characteristic professional manner. These things very possibly actually glue together the pieces in the framework of his treatment, and still, little question or no question arises in his mind as to their special nature and origin, their relation to himself and to his patient. For him these original, most ancient elements in the art of treatment operate in an almost wholly unconscious manner and of all of the elements that enter into his total program of treatment, they alone are excused from scientific scrutiny. By this I do not mean to say that practically he may not be a good doctor but about no other matter in his treatment armamentarium would he be content to be so ignorant. A skeptic in all else he accepts on faith and as a fact needing no investigation that somehow he has been endowed with the gifts and grace that make him a good physician. When his remedies and techniques work his faith is displaced on to them. His sincere belief in the efficacy of his material agents and his procedures may work wonders for his patients. If his belief is shaken, the wonders may cease.

When I was an intern and resident physician, long before the days of specialty examining boards and with never a psychoanalyst in town, much less a psychoanalytic institute, there was on the attending staff of the Cook County Psychopathic Hospital, a sincere, skillful, kindly and learned physician, thoroughly trained in neurology and psychiatry in his native Germany at the end of the last century. His was one of the largest practices in the city. Nevertheless, he faithfully gave much more time to charity service and to teaching in the hospital than many newly graduated residents do nowadays. In his practice were many psychoneurotic patients. To him the psychoneuroses were physical disorders

with mental and emotional manifestations. He thought there was some deficiency of those usual organic resources of the organism which should have been present to enable it to meet life's stresses. He had three sovereign remedies,—one was an organic form of iodine, presumably especially effective in supporting the activity of the thyroid gland ; a second, sodium cacodylate by injection, the arsenical content of which increased the viability of the red cells ; and the third, two gradations of strength of a sedative mixture to quiet the nerves. These two mixtures came to be known by his name and were procurable at Sargent's Drug Store under the appellations of Dr. X's mixture Number 1 and Dr. X's mixture Number 2. After his first careful examination, his subsequent interviews with patients rarely lasted much beyond ten minutes but were very effective in maintaining results. He inquired as to his patient's symptoms and as to how the directions he had given were being followed. All was carefully written down. He then commented on progress or lack of progress, with his statement of the reasons therefore, and the explanation and revisions of directives until the next visit. Then the sodium cacodylate was injected and as the patient was escorted to the door, the doctor would make some such remark as, "My boy, you are doing well but you should watch how you take your medicine. You come back next week." There is no question that his patients benefited greatly from his treatment. When the doctor was away on his summer vacation, I took his office practice for him ;—and I know they loved and respected him, and that they felt he helped them much. He went to Germany on a visit, and, as I was then in practice, he directed his patients to come to my office and supplied me with full information as to the management of their treatment. While abroad, he died and I fell heir to a practice which I lost entirely in a short time. Somehow, though I attempted scrupulously to honor his memory by treating his patients exactly as I knew he would have wished and as they were prepared to expect, their symptoms grew worse and the remedies were without effect. The patients had an explanation and it was correct, though they didn't really know

just how it was correct. They would tell me something like this : "No, the medicines are not the same. I know you think they are but they can't be. Old Dr. X had some secret thing he put into them that he didn't let you or anyone else know. He expected to come back and now the secret is buried with him." As the years went on I became convinced that they were not far wrong in their judgment. He had a secret ingredient no druggist could put into a prescription. Only he had the power to include it and its inclusion was a secret even from him. It died when he died.

It is the favorite complaint of many psychiatrists that there is a resistance to the teaching of psychiatry and, by and large, this means the teaching of psychotherapy and the concepts to which it is related such as psychodynamics, psychogenesis, and psychopathology, on the part of many non-psychiatric teachers in the medical college. When a program of psychiatric teaching as attempted in cooperation with another department does not work well, the reason is often seen as being a kind of sabotaging lip service overlaying subversion both conscious and unconscious. This reason may apply at times. I am sure that instances can be found which will seem to justify the conclusion. *Nevertheless, the fact remains that psychiatry has not made its point that psychotherapy is an essential ingredient of all medical practice and that understanding of the fundamentals on which it is based is a necessary part of the preparation for all medical practice.* We cannot, in justice, place the chief blame on everyone but ourselves. It must be remembered that, as with the discovery of many of the elements in the atomic series which have been at work practically in the processes of nature since the beginning of the world and whose existence and applications have been only recently discovered, with the elements which enter into psychotherapy, much of the discovery, and this discovery is still in the early exploratory stage, has been made recently. There is a good deal of resistance among psychiatrists themselves to looking into this subject without bias ; otherwise, we would not hear talk of a medical psychiatry as opposed to some other kind of psychiatry. Actually, there is no other kind of psychiatry than

medical psychiatry. *Psychiatry includes many elements and a psychiatrist to be a complete psychiatrist should have sufficient knowledge of the nature, mixture, and effects of all of these elements.* Psychiatric medicine contains elements which are a part of all medicine.

In this connection, I must again refer to the demand created by the public need, a demand which is becoming more and more apparent as the practice of psychiatry returns to its proper focus—the individual in his proper setting, his own community. Last year Dr. Solomon spoke of the impending doom of the large state hospital. It may be that he is correct though I am still not prepared to say that this is the case. We do not as yet have means of curing all forms of mental disorder. We do have somewhat improved means of dealing with the ones that at present defeat our best efforts at securing really effective treatment results. It is conceivable that large hospitals divided into efficient operating units may serve a very useful purpose. Practically, we are not in a position to abandon them as yet.

In the survey of every means of treatment which has been used in mental hospitals, whether large or small and whether the treatment involves hydrotherapy, insulin, electric shock, tranquilizers, group therapy, or the open hospital, one thing stands out high as the peak of Mount Everest,—every time there has been benefit, we discern people striving earnestly and mightily to help other people, watching with interest everything that happens, noting above all the patient's sense of status and comfort and the ease and naturalness of his relations with other people, his attentiveness to social requirements and to taking his place in the scheme of things as do his compeers. These are the principal tests by which the success or failure of therapy is judged. These tests also suggest to us the need for understanding the operation of all of the factors which lead to the results. These are the factors concerned with the thinking, the feeling, the manners and attitudes as found within the patient and as they are related to the thinking, feeling, manners, and attitudes of those about him. Extend this kind of thinking to all types of medical practice and medicine

in general will cease to be so much devoted as it is now to material and technical preoccupations. The emergence of psychiatry from the special psychiatric institution indicates that a change in direction to the community is taking place. We now have a private office practice of psychiatry, the number of mental health clinics has increased enormously, more and more general hospitals are establishing psychiatric units, private mental hospitals are being more and more converted into non-profit institutions, insurance organizations are slowly but steadily giving ground in the payment of benefits for mental illness. The psychiatrist, as a consultant and as a cooperating practitioner, is working more and more closely with other practitioners of medicine. His ideas and methods are surely, even if slowly, gaining wider acceptance. The defense of his methods and his ideas is being undertaken more and more readily by a great number of people within and outside of the medical profession. This being the case, he ought to be as well prepared as possible to render the services expected of him. Therefore, his preparation for practice should receive some attention. Some psychiatrists rather pridefully refer to themselves as organicists probably in reaction to other psychiatrists that they regard as "too psychoanalytic." Now, every psychiatrist in some measure should be an organicist, but no psychiatrist should aim to be exclusively one. He could not succeed in that aim. On the other hand, no psychiatrist should be so purely psychologically oriented that he is content to give merely lip service to the fact that human beings are definitely living organisms and affected by physical conditions including physical means of treatment.

Part of the resistance to the acceptance of psychotherapy and to the grounds upon which it rests has been a too theoretical exposition of these grounds, often with unnecessarily unfamiliar terminology and much reference to mythology. Psychopathology, psychogenesis, psychodynamics, and psychotherapy are things not detached from the living, physical man. While I feel safe in assuming that there is no physical disease without its mental and emotional components, I am still safer in saying that no disembodied psyche ever came into my

office. Common accusations made against psychiatrists concerning their attempts to present a rational view of psychotherapy are that they are too much inclined to test their own theories quite subjectively, too deterministic in their views, the determinism being conditioned exclusively on the basis of their theoretical concepts and allowing too little for exceptions, too inclined to judge maturity in terms of psychosexual development, and to regard all variants of behavior as abnormalities. Above all, the techniques and methods often considered to be of the greatest psychotherapeutic significance, and especially orthodox psychoanalysis, are commonly ones that are extremely time consuming, expensive, and therefore applicable only to a highly selected group of people suffering from a very limited category of psychiatric indispositions and illnesses. The doctrinaire system in fixed form and without modification will follow the fate of all the special systems. It will not find a lasting place in medical practice. I think we can count upon the fact that medicine will tolerate a system in fixed form and without modification for only a very limited period of time. It has always borrowed freely from any source it chose. This must apply in the case of special systems of psychiatric treatment. It will select from them the things that have been proved of value in use. Many things often urged as of essential importance are adventitia related to but not of the essence of psychotherapy as a physician must know it and use it. It is a thing he must know in its essential characteristics, not something he must be loyal to as a system of orthodoxy.

Psychotherapy is not easy to define. There may be some individual who feels he has defined it satisfactorily. When groups of persons skilled in its use and well informed as to current theory concerning it attempt to define it, the attempts turn out to be quite unsatisfactory in the result. There are certain describable characteristics which are generally acceptable. I believe that these must be the departure points for explorations.

It is a method which involves communication between patient and doctor; it is a method in which feeling and emotion play a large part. The object of the communica-

tion is ostensibly to give the doctor as complete, honest, and confidential a view of the patient's interior workings and history as it is possible to obtain. This is for the purpose of enabling the physician to understand the motivations of the patient's internal operations which may be related to the production of symptoms. Due deference is made to the patient's need to understand also but since the patient does not have the physician's experience to provide him with criteria and standards of comparison, it is very doubtful that even in successful psychotherapy his understanding of himself will be very complete. From the viewpoint of feeling and understanding, it is not a one-sided operation involving the patient exclusively. The physician does have a requirement resting upon him at the very beginning of psychotherapy which, while different from that resting upon the patient at that time, nevertheless exists and must be recognized. The physician will have to have objectivity and understanding, not only about the process of treatment which he is using but also about himself, particularly with reference to his own emotional motivations. This is extremely important for he has to guide and control the application of the therapy and the steadiness and sureness of his technique here is as important as the sureness of the surgeon's technique in the guiding of a knife. Confidentiality of communication is an essential to gaining a clear view. It is also an essential for allaying the patient's fears. The understanding of the emotional aspects of psychotherapy becomes more and more important as the therapy proceeds and a special emotional relationship is built up between the therapist and the patient in which the patient practices upon the therapist and others his habitual and often misdirected behavior while the therapist attempts to aid the patient achieve better behavior. In the process of psychotherapy repeatedly there comes to attention the importance of the closer, significant human relations of the patient's past and present in their bearing upon the patient's development and conditioning as to behavioral reaction in all new relationships.

There are many pitfalls and dangers in applying a therapy based upon such principles. Also, the techniques by which it may

be learned and the techniques through which it may be applied are time consuming and somewhat complicated. Consequently, teachers of medicine are often inclined to seek short-cut methods which will give them a speedy index of what is presumably wrong with the patient and short-cut methods to correct what is wrong effectively and promptly. Unfortunately, this cannot be done, at least very often. The result may be abandonment of all attempts at rational psychotherapy and the use of intuitive procedures only. This happens in spite of the fact that, as I have stated repeatedly, the physician-patient relationship, the importance of the physician as a person in the patient's eyes, have always been recognized in medicine as being of transcending importance. This alone would seem to indicate that the relationship implicit here deserves intensive and intelligent exploration.

Should medicine ignore the obligation to study the scientific basis for psychotherapy and all that is implied in the study of this scientific basis, then that study and the applications deriving from it will be the work of others not medically trained. Psychologists have been engaged in research in this area for some time. Some of our states have licensed clinical psychologists for the practice of psychotherapy. The most ancient ingredient of the medical prescription, the mother ore of psychotherapy, is being refined for use as a modern, rational psychotherapy. How much of the refining and how much of the use of the refined product will be the task of others than physicians remains to be seen. When the effectiveness of a remedy in treating human ills is clearly evident, medicine never fails to appropriate it. This furnishes the chief assurance that psychotherapy will remain in the province of medicine. There was a day when leading obstetricians scoffed at the idea that puerperal fever was carried from patient to patient on the hands of the accoucheurs. In the light of evidence opinion and practice had to be changed. The evidence as to the scientific respectability and practicality in application of modern psychotherapy is beginning to be appreciated.

Intensive study of psychotherapeutic procedures and of their results is going on

in many research institutes. The problem of establishing scientifically valid controls and methodology is obviously difficult. Psychologists are contributing no small share to these investigations. For the third successive year the Hofheimer Award of our own American Psychiatric Association has been given by an all-psychiatric jury to a psychologist. In the field of practice, clinical psychologists are no longer content to engage only in diagnostic testing. They wish to practice psychotherapy and they do, under medical supervision and without it. Its nature and quality are open to question. Psychologists, themselves, assert this to be the case, and state that it is one of their reasons for seeking some measure of legal control through certification or licensure laws. Meantime, physicians, including the psychiatrists, are unable to meet the demand for giving psychotherapeutic aid to patients in the office, the clinic, the hospital. If the psychologist offers his service to an overcrowded and understaffed state hospital, it is vain to protest unless one is able to provide something better. On the contrary, this aid is often welcomed,—and by the psychiatrist. Usually in the medical institute and clinic this is the case. The issue which exists between physicians, and at this moment the physicians are chiefly psychiatrists, and clinical psychologists concerning the practice of psychotherapy will not, in my opinion, be settled satisfactorily along organizational and political-legalistic lines. License to practice medicine came only after experience had demonstrated the values of medical treatment and the need for qualification through medical training and experience to deserve that licensure. License is a right only in a limited sense. It is a privilege earned. The physician must never be in the position of fighting a privilege which may possibly be accorded to others on the ground that it is his exclusive right to enjoy that privilege. Licensure laws are based on the principle that the citizens of the state are the ones to be protected. They grant rights to those licensed in view of this and they place certain obligations and responsibilities upon the licensee as to special preparation for rendering a type of service. The license may be for a limited kind of service or it may be a broad license. The license to

practice medicine is a broad one. It is the result of a long process of growth of the medical tradition. It presupposes a code of ethics, and a broad-based understanding of everything involved in the causation and treatment of human illness. It is an extensive license because it also presupposes that the profession of medicine will ensure that its practitioners are the best prepared in their day and age to offer the best that can be offered to fight the ravages of illness. No other license in the field of treatment is as extensive as ours. The obligation is upon us to bear the responsibilities entailed in licensure as well as to enjoy the privileges. Understanding of the scientific basis of psychotherapy will require continued experience in application and intensive research. I am sure that within the field of medicine we shall give it just this which it requires. I cannot believe that treatment can be divorced from the full resources of diagnostic procedure. These procedures involve the body and the mind whether either the body or the mind seems to be sick. That psychotherapy can be given effectively without due consideration to the full basis for training in diagnosis does not seem reasonable. It is true that it may be delegated to others as a technical procedure but, if it is, we do not escape our obligation to the patient to see that it is properly managed and supervised. It cannot be a matter of "you do that and I'll do this," a partitioning of practice involving divorcing of responsibility. It is difficult for me to understand how a physician who feels himself incompetent to evaluate the need for psychotherapy except on grounds of exclusion of presently existing physical illness and who wishes no acquaintance with its techniques can give adequate supervision of psychotherapy to one he asks to render the technical service. He would be in a better position to do so if he possessed a goodly measure of the knowledge of psychotherapy, of the foundations upon which it rests, the indications for its use, and the controls which should be applied to it. Psychotherapy has a place in the armamentarium of the physician. It is not to be taken for granted as being a natural characteristic or gift of a physician consisting only of such things as intuitive perceptiveness, an ability in hearty

reassurance, persuasive argumentativeness, facility at suggestion, opportunistic manipulation, bedside manner, or parade of scientific knowledge at the head of a military-like procession as medical rounds are made. Such things may often appear impressive. They do have their effects—sometimes good, sometimes bad—but they do not truly justify the name of psychotherapy as a physician should know it in this day. I will not pretend that anyone understands fully and completely any of the operations of the human organism and that anyone has finally and completely perfected any treatment procedure. This statement applies in the case of psychotherapy as it does to other therapy. At this time there is available much information and understanding of what psychotherapy involves. This information and this understanding should be possessed in its general form and be used intelligently by everyone who merits the name of physician. Full medical service to the sick of the land requires this. Medical education should accept the obligation of providing it.

Medical practice, the treatment of the sick, has been built about two things, the knowledge and understanding of human beings,—body and mind, and the unique characteristics of a physician-patient relationship. All else, the material agents and the procedures for their use have been added to the essential nucleus. These added things may change very much from age to age. The essential center remains from age to age. This center may be looked upon as the mother ore for psychotherapy. Thus, psychotherapy is to be accepted as an essential element of all medical practice. To be of most use the ore needs benefit of the most scientific refining possible. This is a task to which psychiatry has set itself and from which all medicine should profit. There is an increasing need for rational psychotherapy and the mandate is for medicine to supply it. No other kind of professional practice so fully encompasses the mortal requirements of the body—mind—soul entity known as man when there is sickness. Goal setting in medical education should be determined in the future much more by these considerations than it has been in the past. All physicians, regardless of the

specialty they practice, should have utilizable knowledge of psychotherapy. This should result in elevation of the status of the general practitioner and in deemphasis

of technical subspecialization. A movement toward such results is necessary if the physician is to remain in a position of public respect and professional prestige.

FRANCIS J. GERTY, M.D.,
Eighty-fifth President—1958-1959 :

A BIOGRAPHICAL SKETCH
FRANCIS J. BRACELAND, M.D.¹

He is at home in any society, he has common ground with every class ; he knows when to speak and when to be silent ; he is able to converse, he is able to listen . . . he is a pleasant companion and a comrade you can depend upon.

—NEWMAN

Trotter in his biographical sketch of John Hunter declared it idle for the common man to try to explain the successes and failures of greatness but he conceded that it was not presumptuous to examine the circumstances of an individual's life for light upon his career and accomplishments. As we examine the life of Francis Joseph Gerty, we appreciate that his heritage and early circumstances give eloquent and prophetic testimony of his future accomplishments and the manner in which he would receive honors and undertake the tasks entrusted to him.

It is possible to follow the weddings and peregrinations of the Gerty forbears back through the seventeenth century. There were Spanish and French and French Canadians, and an ever so generous admixture of Irish among them. We find them settled in Chicago long before Mrs. O'Leary's cow had her disastrous encounter with the lamp. The marriage of Frank K. Gerty and Josephine Vincent Gerty, was graced by 5 children and Francis J. the eldest, was born November 17, 1892. A younger brother, A. Vincent Gerty, a Fellow of The American Psychiatric Association, and one-time superintendent of the Los Angeles County Psychopathic Hospital, is presently practising psychiatry in Pasadena, Calif.

BACKGROUND

Gerty, père, an alumnus of the University of Illinois, was a school master, dedicated to his calling. After he was promoted to an administrative post he continued his educational work by tutoring immigrant boys and also held educational court in his home

on week end evenings. His son Francis was one of the beneficiaries of his love of pedagogy and before the boy had finished grammar school he had acquired from his father a basic knowledge of literature and mathematics, an understanding of what and how to study, and most important of all he learned the love of books, a priceless gift he was always to cherish.

From a gracious mother the Gerty children learned many things, among them the virtues of basic friendliness and kindness and also they were taught *en route* by precept and example that most obstacles could be overcome. Though there was a consistent serenity in the maternal make-up, there was also a determination that her children should succeed as individuals, as well as acquire an education. Fortunately she lived to see these aims accomplished.

There are many stories of the young man agrowing, too numerous to mention here. There were various jobs, hobbies and enterprises ; one of the latter might have had prognostic value. While serving as a delivery boy at the age of 13, he figured out a way to ride trolleys all over Chicago by a judicious use of transfers for only one nickel ! Seemingly he was fitted for a financial career.

Graduating from the Chicago Public Schools in 1906, Englewood High School in 1910, Chicago Teachers College in 1912, the youth launched on a teaching career in the Chicago schools in the family tradition. He taught first in the grammar grades but later changed to the vocational arts for two reasons, one, the love of doing things with his hands, and two, the vocational job paid better by far. Also, by now he had decided that medicine would be his

¹ Inst. of Living, 200 Retreat Ave., Hartford 2, Conn.

bodies and with numerous demands upon his time, he is superintending the building of a new house, mostly, his good wife states, *in absentia*.

Dr. Gerty's public activities embrace all of the advisory psychiatric positions to the Illinois authorities, the most recent being that of Chairman of the Illinois Psychiatric Council. Also he holds appointments on the Psychiatric Training and Research Authority of Illinois, a statutory body and the first of its type. His hospital appointments start back in 1923 and include Mercy, University, St. Lukes, Hines, Cook County, and now the Chairmanship of the Department in the new Presbyterian-St. Lukes Hospital.

It is interesting that, except for an occasional excursion into A.M.A. tasks and as a consultant to the New Mexico state hospitals, most of his work had been kept within the confines of his native state until the late forties. It was not until the years following World War II that he began to appear regularly with the national bodies. Soon it was established that when there was a difficult task to be performed, one sought Dr. Gerty to do it, whether it concerned the introduction of an orator whose words would be sure to cause unrest, or the discussion of the paper of an individual who was controversial. As chairman of a committee to evaluate the role of psychoanalysis in psychiatric training in the Cornell Conference, he distinguished himself by his statesmanlike conduct of an inquiry into a subject which needed expert and careful examination and won national repute. He was in demand for all types of duty. The Group for the Advancement of Psychiatry, the Section on Nervous and Mental Diseases of the A.M.A., the Central Neuropsychiatric Association, the Advisory Councils of the U. S. Public Health Service and the Veterans, the American Board of Psychiatry and Neurology, chairmanship of the Committee on Medical Education, the Council, then President-elect and then President of The American Psychiatric Association, plus the Presidency of the American Board of Psychiatry and Neurology at the same time. To all of these tasks he lent his wise judgment and dedication and he won the respect and admiration of his col-

leagues. In the search for biographical data, while people were questioned whose beliefs diverged widely from his, none was found who did not pay high tribute to him as a physician, teacher, administrator, and as a man. One noted colleague from a foreign land, whom Dr. Gerty had befriended, noted how skillfully he protected his researchers from political interference and secured funds and opportunity for them to carry on their work. He says: "The way he 'kept' his scientists reminds me of the Medicis who gave every possible support to the artists they engaged but left them free to work according to their own fantasy. There is something in this man's character that resembles the great figures of the Renaissance."

Dr. Gerty belongs to all of the important local and national medical and psychiatric bodies. He was elected to AOA, Sigma Xi, and Blue Key, all honorary societies. His publications run the range from those done in collaboration with G. W. Hall in 1923 on *Folie à Trois* and in 1927 on *General Paresis*, to those in 1957 on *Biochemistry of Schizophrenia* and on the *Individualization of Treatment in the Aging*. Between these there are numerous publications on history, on the civil law, on phosphorus metabolism—even one, believe it or not, on the *Clinical Effects of Moonshine Liquors*, done for the *Public Health Journal*.

Dr. Gerty is a devout man, secure in his own beliefs and completely respectful of the presence or absence of belief in others. In 1957 he was honored by Pope Pius XII and was made Knight of St. Gregory the Great. In the same year Loyola University awarded him the degree, Doctor of Science, *Honoris Causa*. Among the finest of things are those which point out that he is a family man, with a deep love for his wife, his children, his home, and his friends.

Perhaps the statements of two men of widely divergent viewpoints, neither of whom is given to flattery or hyperbole, will typify the regard in which Francis Gerty is held by persons of all persuasions. One, an internationally famous psychoanalyst, says of him: "All in all he is a liberal in the best sense of the word. Extremely aware of and resistant to any undue infringement

on the spiritual freedom of the individual, without being a rebel in the least, he is a leader *par excellence*." The other, a distinguished neurologist and neurosurgeon, says: "His devotion to the public cause, at great sacrifice to himself, is a matter for emulation on my part. It will be a sad day for psychiatry in the State of Illinois when he disappears."

It has been said that the great lesson of biography is to record man at his best and

that a noble life put fairly on record acts as an inspiration to others. In the case of Francis J. Gerty this is certainly true. Those of us whose privilege it has been to work with him and to watch him skilfully handle difficult situations with consummate kindness and tact realize that he is strong because "he has the repose of a mind which lives in itself while it lives in the world and which has resources for happiness at home when it cannot go abroad."

HUNGARIAN REFUGEES: LIFE EXPERIENCES AND FEATURES INFLUENCING PARTICIPATION IN THE REVOLUTION AND SUBSEQUENT FLIGHT¹

LAWRENCE E. HINKLE, JR., M.D., FRANCIS D. KANE, M.D.,
WILLIAM N. CHRISTENSON, M.D. AND HAROLD G. WOLFF, M.D.²

During the period from December, 1956 through September, 1957, 69 Hungarian refugees were interviewed, examined, and observed at the research facilities of the Human Ecology Study Program, in New York.³ The group of informants was carefully chosen to include students, scientists, members of professions, intellectuals, skilled and semi-skilled workers and adolescents, whose motives and behavior were of special interest because of the leading role that such people had taken in the Revolution of October, 1956. Only a few former landowners and members of the old middle class were included. Some of those studied had held positions of trust and responsibility in the Hungarian Communist State, and had been favored members of the society. Many had been acceptable to the Communist Party, and had been associated with its ancillary activities, although they were not actually party members. In order to have data from former Party members also, some of the staff of the Study Program went to Great Britain in the summer of 1957, where they tested, interviewed, and examined 7 additional refugees who had been active Communists, some of whom considered themselves still to be so.

The goal of the investigation was to determine, as far as possible, the factors that had had an important influence upon the behavior and health of these Hungarians. It was, therefore, a study of individu-

als, rather than of the group as a whole, and our conclusions are chiefly pertinent to the behavior of these individuals; however, some of them undoubtedly have a wider general applicability.

The investigation was based upon the hypothesis that the behavior of a man is determined by his constitutional characteristics, his cultural background, his position in the society in which he lives, his developmental experiences, his later life experiences, and his total life situation as this is perceived by him. The procedures were designed to gather data in each of these areas. They included an assessment of the constitutional characteristics of each informant, a careful and extensive chronological life history, a detailed history of all of his illnesses, interviews with sociologists, psychiatrists, and a cultural anthropologist, a series of psychological tests (including the Rorschach, Wechsler-Bellevue, TAT, a projective questionnaire, and a sentence completion test), a physical examination and a period of observation during an informal evening's entertainment. The whole investigation required two days of each informant's time. Each became a source of information about the attitude and behavior of the groups of which he was a member, as well as about his own behavior during his lifetime.

A good deal of effort was focussed upon an attempt to determine why these people fought and fled. The observations give no support to the idea that the revolution and the subsequent exodus were simply the result of the unpremeditated action of people swept up in a wave of mass emotion. On the contrary, they indicate that those who participated in these events had long-term, deep seated, realistic, and highly personal motives for their actions. This was true of nearly everyone studied, regardless of his background or behavior; it was such a regular observation among the students, adolescents, workers, teachers, scientists,

¹ Read at the 114th annual meeting of the American Psychiatric Association, San Francisco, Calif., May 12-16, 1958.

² From the Study Program in Human Health and the Ecology of Man, Departments of Medicine and Psychiatry, New York Hospital-Cornell Medical Center, New York, N. Y.

³ Among those who participated in these studies were Eva Bene, Ph.D., Sandor Borsiczky, M.D., George Devereux, Ph.D., William J. Grace, M.D., Ari Kiev, Maria H. Nagy, Ph.D., Thomas J. O'Grady, Jay Schulman, M.A., Richard M. Stephenson, Ph.D., and William N. Thetford, Ph.D.

and professional people that there is very good reason to believe it is true of the refugee group in general.

Their motives fell into two general categories. The first was a long-term and insurmountable feeling of personal insecurity—an implicit belief that, "No matter what I do, or how high a position I may attain, I and my family may be ruined at any time by the actions of others, or by events beyond my control." The second was a profound sense of frustration—a deep-seated conviction that, "In Communist Hungary there is no way that I can live out my life as I want to, and in a manner that satisfies my needs." The motives of the individual refugees were not based primarily upon irrational and generally shared prejudice, upon unformulated fear, or upon abstract political or religious convictions; they were based upon personal experiences with confiscation, denunciation, arrest, imprisonment, and the denial of jobs, housing, and education. Such motives were as strong in those who had been ostensibly favored by the Communist Government as they were in those who had been officially designated as "class aliens."

None of the informants—not even those in a position to be well-informed—had expected the revolution to occur when it did. No group had planned it. The great majority of the informants had not been aware that many other Hungarians felt as strongly as they did. Yet all had been aware of their own intense dissatisfaction for many years past, and a very significant proportion of them had privately decided, long previously, that they would flee from the country, or take part in rebellion, at the first opportunity. In this, many of them were supported by their families—even by family members who knew that they would be left behind. Thus the fight and flight of an individual might have been sudden, but his behavior was not unrealistic, and often not entirely unpremeditated.

Economic deprivation was a poor determinant of behavior. Some of those who participated most vigorously in the revolt were people who were economically better off than they might have been under the old regime, and knew it; others, including members of the old middle class and former

landowners, who had been reduced to subject poverty, took no part in the fight but simply fled. The group as a whole was relatively little concerned about the economic organization of the society. Their resentments were focussed upon its "police state" aspects—its arbitrariness, restrictions, brutality, and unpredictability.

Only a minority of our informants had participated in the actual fighting, although all had sympathized with the revolution and many had supported it tacitly or by ancillary activities. Those who took up guns and fought regardless of the consequences were people who readily acted out their hostile and aggressive drives. In general they came from segments of society in which fighting is acceptable behavior; they were adolescents, working people, former soldiers, and former political prisoners. Writers, teachers, scientists, and professional persons confined themselves to organization, propaganda, supply, communication and like activities.

The group as a whole displayed a deep-seated hostility toward Russians. This had been strongly reinforced by Russian behavior during the past 15 years; but there was much evidence that anti-Russian attitudes existed in their parents before World War II, and that the younger generation had derived their own attitudes primarily from those of their parents.

They had a similar hostility toward the people who made up the central Communist Government group, and toward many of the local functionaries and hangers-on. Attempts by the Communists to indoctrinate young people, students, and workers by means of propaganda, education, and other activities had been singularly ineffective in eradicating such attitudes. Even favored young members of the Communist Party—students and intellectuals who were relatives of prominent Communists, who had grown up in the Party, and who had no real memory of life as it was before 1947—were disillusioned and bitterly opposed to the Communist system. They had learned to form their beliefs and attitudes from what they saw and knew, rather from what they heard or read. They regarded some socialist economic reforms as desirable, but for Communism and Com-

THE SALIVARY CURVE: A PSYCHIATRIC THERMOMETER?¹

GEORGE F. SUTHERLAND, M.D.³

The remarkable sensitivity of the salivary secretion in reflecting the internal and external milieu, led us to wonder if it might be adapted as a clinical adjunct to measure the emotional status. The observations presented are taken from a larger study concerned with the investigation of "internal inhibition" (in the Pavlovian sense of the term) by the method of conditional reflexes. They are merely incidental findings and do not constitute a coordinated attack on a particular viewpoint. They are presented in the hope that they may stimulate interest in widening the scope of evaluating those aspects of emotional life that have proven so elusive when attempts are made to reduce "impressions" to a more concrete form. The record of the flow of saliva may be likened to the electroencephalogram which, though not strictly mathematical in form, nevertheless can be compared with others taken in a similar manner.

The salivary conditional reflex, I fancy, was not chosen by Pavlov as a subject for study because of some inherent property that gave access to the secrets of nervous function but rather because of his continuing interest in the digestive processes. Nevertheless, it has much to recommend it as a medium of investigation. Without requiring any operative interference the parotid secretion is readily available in man for recording purposes by means of a small suction capsule(1) applied directly over the opening of Stensen's duct. (Fig. 1) The types of stimuli required to induce a flow of saliva are specific and can be controlled. They fall into two groups: those concerned with alimentation and those directed toward combating irritants. Ordinarily the reflex is not subject to acts

of will, thus eliminating random or deliberate activity that so frequently complicates the interpretation of motor defense reactions. On brief stimulation the reflex is elicited promptly, usually in one or two seconds, and its effects continue for some 8 to 10 minutes, allowing detailed observation but still falling within the convenience of a daily experimental session consisting of from 4 to 6 combinations of signal plus reinforcement. The response is determined not only by the specific stimulus but also is subject to modification by the internal and external milieu which makes possible the opportunity to measure these factors. Finally, the salivary reflex offers a bridge to collate the traditional Pavlovian work in animals with analogous studies in man.

The failure to demonstrate the conditional salivary reflex on the part of many investigators has been attributed to the readiness with which inhibition is developed by the human subject. It is this same facility of elaborating inhibition that offers the advantage in this investigation. Actually we have experienced no difficulty in demonstrating the reflex. Technique and instrumentation are probably the answer. From a technical standpoint the difficulty is about the same as that of recording the electroencephalogram.

Recently I was surprised to read the statement by Bykov(2) that many investigators, including Gley(3), Langly, Winsor and a number of the Russian neurologists failed to form a salivary conditional reflex in an adult individual.⁴

Fig. 2 illustrates a conditional salivary reflex in an adult and this is not a single example by any means. I doubt that it is much more difficult to demonstrate the salivary reflex in man than in the dog. I would point out that in animals one usually

¹ Read at the 114th annual meeting of The American Psychiatric Association, San Francisco, Calif., May 12-16, 1958.

² This study made possible through the cooperation of the Research Department of the Spring Grove State Hospital, with assistance from Friends of Psychiatric Research, Inc.

³ Chief, Division of Psychiatric Education & Training, Department of Mental Hygiene, State of Maryland, Baltimore, Md.

⁴ I could not help noting that the formation of the reflex in children was accepted presumably because Krasnógorsky(4) had written on the subject but come to think of it I do not recall if anyone since has confirmed the work. This brings to mind an amusing incident that occurred while I was working in Montreal in the early thirties. L. Andreev, from Pavlov's laboratory was also there at the time as an

chooses a "good secretee" and by the same token discards those that fail to answer the purpose as readily. From a medical standpoint this cannot be done in man, especially in the case of patients, if the results are to be statistically valid.

It seems true that inhibition is much more easily mobilized in man than in animals but when attention is paid to this fact there is no question that conditional salivary reflexes can be formed and demonstrated under laboratory conditions. In fact, there is no way to prevent their being formed—it is in the demonstration where the difficulty apparently lies. Anyone familiar with the technique of the conditional reflex method is shocked to see the recklessness with which the average laboratory procedure is carried out. Extraneous stimuli are at work and it is inconceivable that they fail to play havoc with the finer nuances of the technique. I am convinced that a whole world of information is consistently—one might even say deliberately—missed. The argument that there is no time for *fol-de-rol* in a clinical setting loses its validity when one considers how often inconclusive or even misleading procedures are repeated in an effort to arrive at a definite conclusion.

The demonstration of the conditional reaction in a laboratory requires more than the usual vigilance accorded clinical procedures. It must be realized that the whole thing is an artificial setting designed to isolate a single element in the psychological field and relate that to an unconditional reflex. From a physiological standpoint this is a most tenuous link temporarily established and it is not surprising, therefore, that its most striking characteristic is its variability. This shows itself in the prompt variations in flow that ensue in response to minute changes in the environment. Tandem experiments

exchange professor. On one occasion I told him that I proposed to use cats as subjects for motor conditional reactions. He said that the notion was laudable but warned that it was futile because it had been found in the Pavlovian laboratory that they could not be used as subjects in experimental procedures. After a few weeks had elapsed I demonstrated the motor reflexes (similar to those shown in the motion pictures by Masserman), whereupon he smiled and vouchsafed that Canadian cats were different from Russian cats!

demanded that I use only cats that had been brought to the laboratory from the same source. I was never informed that in any manner it is easy to identify a cat's reaction as being ill because of some factor in reaction to both subjects. The following is an example of these peculiar reactions and one in which, though, by one of the subjects, could be identified by the observer. Frequently it would appear that the observer passes unnoticed by the subject as well as "subliminal perception". This sensitivity of the secretion rather than being regarded as a hazard is probably the chief attribute that enhances its value as a measure of factors that are influencing the function of the organism, perhaps even subconsciously.

To demonstrate the conditional reflex in the laboratory one must guarantee a relatively uniform environment and a rigid adherence to the technique which includes every influence that might affect the subject's psychological field. The nervous system takes note of every stimulus that impinges upon it whether or not it happens to be included in the protocol.

With regard to the conduct of the experimental procedures a word should be mentioned with respect to instrumentation. Since the flow of saliva in man is rather small in response to brief stimulation a liquid-filled system is desirable for transmitting the minute changes in pressure from Stensen's duct to the recording apparatus. An air-filled apparatus because of its slight inherent compressibility will usually fail to pick up the instant the salivary flow is initiated and as a result no record of the conditional response is obtained, or else inordinate delay distorts the time components. The whole curve will be smoothed out, thereby losing the detail of the sharp fluctuations in flow. It is virtually impossible to gain an accurate picture of the flow by the simple expedient of observing a manometer rather than having it mechanically registered in the form of small drops. The size of the drops should be of the order of one-hundredth to the cubic centimeter. This accomplishes two things: it records small changes and causes the drops to pass over the electrodes quickly, thus ensuring a prompt registration.

For a laboratory, two adjoining rooms are used situated in a rather remote quiet section of one of the hospital buildings.⁵ During the experimental session the observer remains in one of these rooms but can view the subject in the other through a one-way glass. Fig. 4.

Fig. 5 shows a diagram of the sialometer adopted in these investigations. The saliva is collected by means of a salivary capsule fitted over the opening of Stensen's duct. A single chambered capsule was used with one or two rings concentrically placed to prevent the mucosa from invaginating into the opening and blocking it. A small tube (#190 polyethylene) leading from the capsule conducts the saliva to a reservoir whence the pressure is transmitted through a diaphragm which in turn displaces an equivalent amount of saline through the drop recorder. The electrical impulses are generated when the drop closes the circuit through an amplifier that operates the recording pen.

First, all the air is eliminated from the system, then the capsule is applied and the valves turned as shown in the diagram. After a few seconds the suction will hold the capsule in place and the test can begin.

The principal signal that we have employed is an electric metronome. Reinforcement is supplied in the form of one cubic centimeter of sweetened lemon juice that is conducted from a syringe by a second small tube that opens on the outside of the capsule.

Fig. 6 shows a positive conditional reflex as it is actually registered by the pen. This record was taken on the fifth day of a series, using a member of the staff as a subject. Each daily session consisted of approximately 5 combinations of signal and reinforcement.

Fig. 7 shows the same reflex when transformed into a chart showing the rate of flow of the saliva. Subsequent charts will appear in this form.⁶

⁵ Spring Grove State Hospital, Baltimore 28, Md.

⁶ The problem of preparing a chart showing the rate of flow from the tape that records the drops of saliva is a tedious procedure. The interval between each successive drop must be measured using an appropriate reciprocal scale and plotted accordingly. To obviate this we have recently used an integrating amplifier in tracing the curve directly. The impulse

For each experimental session a protocol is prepared in advance and followed precisely. This is devised to avoid the unnecessary generation of inhibition and to prevent the elaboration of a "time" reflex. To accomplish these purposes the signals for the most part are kept short (3 to 5 seconds) and are repeated at intervals that vary (3 to 8 minutes). When the conditional reaction is to be tested an occasional signal is prolonged (10 seconds to 20 seconds) and the reinforcement delayed proportionately. The duration of the signal is considered as being from the initial sound of the metronome until the application of the lemon juice. To provide continuity the metronome overlaps the beginning of the lemon juice. The application of the lemon juice can be recorded with a fair degree of accuracy but the duration of its effects obviously must be considered variable.

In response to a brief stimulus, saliva is secreted in a series of spurts rather than by a continuous stream as might have been anticipated. The rate of flow rises swiftly to a maximum but then declines by a succession of ever-diminishing fluctuations tracing a curve that lasts about 8 minutes before the baseline is resumed. (Fig. 8) I hasten to add that this curve is seen in its entirety only under perfect conditions but usually one or more cycles are clearly apparent. These certainly correspond to the Pavlovian phases of positive and negative induction. Superimposed on this parent curve are minor recurrent variations of undetermined origin.

The gross contour of the major curve approximates the following mathematical formula:

$$\gamma = e^{(\ln x)t} \sin 2\pi T$$

suggesting that the oscillations represent the fluctuations of a feed-back mechanism whereby equilibrium is re-established. In this connection it is interesting to call attention to the fact that Pavlov alludes to such a homeostatic device⁽⁵⁾ but does not elaborate the subject further.

In 1932 I learned from L. Andreev (per-

initiated by the drop closing the circuit activates a multivibrator that drives the integrator. Simultaneous records of the drops of saliva and the rate of flow may thus be obtained.

onal communication) that the workers in Pavlov's laboratory appreciated the significance of at least the first part of the curve and took cognizance of it in their experiments.⁷

In the quiescent state the baseline secretion is relatively uniform and the experiment in our laboratory indicates that the rate of flow from the parotid duct is from three hundredths to five hundredths (3/100 to 5/100) cc. per minute. It is well known that a high interval secretion in animals is associated with poor positive reflexes. In the "agitated" form of the experimental neurosis where central irritation is the rule, the level of interval secretion is elevated. In the inhibited type the level is depressed. It is no surprise, therefore, that we have more difficulty in demonstrating conditional reactions in patients than in non-patients. The administration of local anesthetics or atropine and conversely local irritants of philocarpine produce analogous effects. Some of the tranquilizers in large doses depress the reflexes and alter the interval secretion. In the absence of extraneous influences we may assume that a consistent departure from the "normal" salivary curve may be attributed to the internal state of the organism.

Our experience thus far indicates that a relation appears to exist between the subjective sense of well-being and the contour of the salivary curve. A change in the curve heralds a coincident change in the internal milieu. It may also be that what we interpret as anxiety corresponds at least in part with "irritation" in the conditional reflex terminology. By contrast central inhibition closely resembles depression. Inhibition may occur in conjunction with many disorders and is not necessarily characteristic of depression in the formal diagnostic sense of the term. One of the more confus-

ing combinations is the association of irritation and inhibition, which if our suggestion is correct amounts to a state of depression.

Fig. 7 shows an example of irritation combined with inhibition and the effect of a sedative. Before medication the secretion is maintained at a high level but there are marked fluctuations seen in the "normal" record. The administration of Amytal gr. 5 tended to restore the regular rhythm.

Fig. 10 demonstrates the effect of one of the new drugs. On the first day after its administration the record abruptly changed from one exhibiting irritation to the antithesis showing inhibition. The record correctly forecast that the choice of the medication was unfortunate, portending that the patient would become more depressed. This was confirmed clinically after a therapeutic trial and the drug had to be discontinued.

The prompt response of the salivary flow to a change in the emotional status was exhibited quite unexpectedly in a patient whose records had previously shown inhibition. One day the record indicated mild irritation. This sudden change prompted the experimenter to inquire if there had been a coincident change in the clinical aspect. At first he was confronted with an emphatic "no" but on pressing the inquiry found out that the morning of the test the patient had been involved in a fight and was the victor in so far as she was moved to a better ward. Following this geographic change the patient's spirits were much improved.

In general it appears that tension or anxiety gives rise to a high level baseline secretion. (Fig. 11) By contrast, depression gives a lower level secretion. (Fig. 12)

Beyond these gross analogies the salivary curve supplies little of diagnostic import to the clinician. On the other hand, even the slightest change in the internal milieu manifests itself promptly, even before the clinical evidence appears. By way of example, the incipient stage of a head cold invariably gives rise to an "irritation" record. One cannot but be impressed with the sensitivity of the method as a reflection of the internal milieu. Perhaps this very sensitivity may be the factor that militates

⁷ From a physiological standpoint it seems probable that this theory offers a satisfactory explanation, not only of this phenomenon but suggests the mechanism by which blood sugar or blood pressure levels are maintained. The only concrete substantiation of it comes from McElroy (6) who describes a similar curve in the maintenance of the enzymatic control of growth processes involving the conversion:

$$\begin{array}{ccccc} & \text{E} & & \text{E} & \\ & \text{ornithine} & \longleftrightarrow & \text{citrinine} & \longleftrightarrow & \text{arginine} \end{array}$$

against its adoption as a clinical measure.

The remarkable constancy of this curve, *other things being equal*, is striking. Nevertheless, it is also true that each record of the salivary secretion tends to be stamped with the pattern of the individual from whom it was obtained. This, of course, is not surprising in view of the fact that the EEG and other physiological phenomena also bear the mark of individuality(7). Since it is not practicable for one experimenter to investigate the conditional reflexes of more than 3 or 4 individuals at the same time, it is usually easy for him to identify those records taken from the same individual merely by inspection. This is not to say that in a large series the same could be done, because of the basic similarity in all "normal" records, in all showing central inhibitions and in all showing irritations. One subject varies from another not only with respect to his level of baseline secretion but also in his specific response to a given stimulus.

Inhibition is so easily mobilized in man that more vigilance is required in demonstrating the salivary conditional reflex than is customarily accorded to laboratory procedures. The little work that has been attempted has been reported chiefly in the early thirties by Russian and Central European workers. There are scarcely any present day references even in comparison with the motor reflex. The same complaint was voiced in 1916 by Watson(8).

SUMMARY

The method offers a most promising field of investigation for those who are prepared to invest the time and effort to learn the

technique. It seems reasonable to anticipate that a considerable saving in time could be effected, for example, in the testing of therapeutic procedures by having recourse to an objective measure rather than impressions that rely upon statistical analysis for verification. It might be mentioned that one "sputnik" is more convincing than all the statistical evidence in the world.

At least one of the more venturesome pharmaceutical companies has already taken advantage of the motor conditional reflex in rats in arriving at suggested doses for each of its new tranquilizers. It is interesting to reflect that the medical profession accept the findings of the drug manufacturers obtained by a less precise method by comparison, yet seem reluctant to explore a much more exact technique in the clinical application of the drugs themselves.

LONGITUDINAL OBSERVATIONS OF BIOLOGICAL DEVIATIONS IN A SCHIZOPHRENIC INFANT¹

BARBARA FISH, M.D.²

Clinical, physiological, and hereditary studies create the impression that a constitutional predisposition to schizophrenia exists in varying degrees of severity, which then interacts with the individual's assets and the stresses to which he is exposed, to produce the many different clinical pictures of schizophrenia. A few schizophrenic children appear to have such a severe predisposition that development regresses in spite of the best family care, schooling and psychiatric treatment that are available at present. The most severely affected patients in Kanner's autistic group fall in this category. Other milder childhood schizophrenics with a pseudoneurotic or pseudopsychopathic picture, show some degree of intrinsic deviation in their development, but the degree of psychological illness which results appears to be much more responsive to family, educational and psychiatric treatment.

Studies of constitutional factors in adult schizophrenics raise objections that the biochemical disturbances which have been found may be either primary predisposing factors, or might be secondary to the prolonged anxiety or hospitalization which has already existed. However, working with schizophrenic children, Bender has pointed out that certain characteristic deviations from normal physiological and neurological development are present in their histories, often at birth (1, 2).

As a first step in investigating possible constitutional factors by prospective studies, a pilot study was begun in 1952 to determine whether biological differences which distinguished schizophrenic from non-schizophrenic children could be detected in the early development of infants.

The author examined a random sample of 16 infants in a Well Baby Clinic that

served a very deprived socio-economic population, and was therefore weighted heavily in the direction of social and psychiatric pathology. From the age of one month, the infants were studied for signs of deviate development. The data from the physical and developmental examinations were analyzed according to criteria drawn from Bender. Accordingly, vulnerability to schizophrenia was defined in terms of 1. Disturbed regulation of physiological patterns, as seen in disturbed physical growth, poor temperature control, vaso-motor instability, allergic phenomena, respiratory and gastro-intestinal difficulties, and disturbed sleep patterns; and 2. An uneven pattern of growth, characterized by unusual sequences and combinations of retardation and precocity occurring in all fields, motor, perceptual, language and social.

The infant, Peter, who showed the most severe disturbance of development and was therefore identified as the most vulnerable to schizophrenia at one month of age and subsequently, is now a schizophrenic child 5½ years old. Three other infants showed lesser developmental deviations than Peter, initially and as they grew older. These 3 children have developed psychological regression readily and have shown more anxiety than any of the 12 infants who developed more evenly. However, the 3 intermediate infants never showed the personality disorganization seen in Peter and they are not considered to be schizophrenic at this time.

Previous papers have presented the detailed clinical observations of these children and their families, the criteria used in the initial rating of vulnerability and the later diagnostic evaluations, and the genesis of the psychological manifestations observed (3, 4). The present paper will focus on several of the biological disturbances seen in the schizophrenic infant, which distinguished his early development from that of the other infants studied and from accepted norms of development.

From the beginning, Peter showed an

¹ Read at the 114th annual meeting of the American Psychiatric Association, San Francisco, Calif., May 12-16, 1958.

² Departments of Pediatrics and Psychiatry, New York Hospital-Cornell Medical Center, New York City.

unusual torporific state and poor muscle tone. He slept more than usual in his first month and moved very little. When examined at one month of age, although he was precocious in some areas, he was lethargic and inactive even when awake and showed a diminished response to sounds and light. He continued to be underactive in large muscle activity until 10-18 months of age when he became hyperactive. Although manual dexterity and strength were adequate for his age in the first year, his movements in reaching and manipulation were performed in slow motion. Only one other baby, Frank, showed a similar disturbance, but to a lesser degree. He slept excessively only for the first week and was underactive only for the first 2 months.

Other aspects of Frank's physical and psychological development were also second in severity to Peter's. The early somnolent state in these infants is reminiscent of the excessively quiet "constricted activity pattern" described by Fries (3, 6).

Peter's abnormal torporific state and lengthy muscle tonus, which were marked during the first 6 months of life, are similar to that seen in normal premature infants until they approach the gestational age of the full-term baby (7). Bender was the first to point out that the existence of such patterns in schizophrenic children represents a persistence of immaturity, "embryonic" features (2). The observations of Peter's abnormal torpor indicate that we must study further the early development of the neurophysiological mechanisms which regulate wakefulness and muscle tonus. We must study the changes in the functioning of the reticular activating system which occur during the development of normal animals and human infants, as well as in the development of schizophrenic children.

A second biological disturbance was Peter's uneven growth which differed from standard norms, from the control infants, and from usual forms of retardation and precocious development. His longitudinal development was unusual, showing both retardation and acceleration, which were most striking in the areas of posture and locomotion during the first year. He held his head up well at one month but was no longer able to lift it at 3½ months, and was

barely able to lift it again at 6 months. This aspect of development actually went into "reverse" in his early months. Control of his trunk lagged so severely between 1 and 9 months that at 9½ months he couldn't sit, and had less control of his body than a normal 5 month old. Yet right after this, development suddenly accelerated so that he was walking normally by 13 months.

The extent of this abnormal development can be seen more clearly when these data are expressed quantitatively.

Figure 1 shows the comparison between Peter's uneven motor development and the relatively even motor development of the other babies. The chronological age of the children is plotted along the horizontal axis. The level of postural-locomotor development at each examination is plotted on the vertical axis, the level being expressed as the age when these levels are "normally" achieved, according to Gesell's standards.

Representative curves of the control infants cluster about the hypothetical "normal" curve, and show relatively even development of posture and locomotion, some children developing faster than others. In contrast, the lowest curve shows Peter's very uneven postural development. This dropped to less than 50% of normal between 3 months and 10 months of age, and then sharply rose to normal by 13 months of age. One must suspect "serious retardation" in a child whose development falls below 65-75% of what is expected for his chronological age (8). The retardation in this infant was well below this critical level.

However, this abnormal postural development was quite different from the usual "slow" baby who shows relatively even retardation (8). Although Peter's motor development dropped well within the defective range by 10 months of age, in the recovery phase which followed, he gained 5 months' development during 2 months' time, showing a rate of development 2½ times as fast as the normal rate. This peculiar retardation followed by unusual acceleration indicates a disorganized postural development, with a fluctuating rate, rather than simple retardation or acceleration. These data suggest that there was a disturbance in whatever central nervous sys-

train mechanisms ordinarily regulate the timing of postural development, and normally results in orderly progression in the dimension of time.

Peter differed in other ways from babies with comparable disabilities. Figure 1 shows the contrast between Peter's abnormal postural development and the normal development of his eye-hand coordination and fine manipulation. This latter skill dipped only at 11 months, to 50% of normal, at a time when he appeared to be preoccupied with exploiting his sudden increase in postural stability. Otherwise fine coordination proceeded normally in the first year at a rate that showed him to be at average intellectual potential. The discrepancy between the furnished development of these two functions produced a picture of "scatter" in his functioning on any one examination.

The general nature of such a picture may become different aspects of development may be seen. This is pointed out in Figure 2, which shows the development of postural development.

Figure 3 compares the timing of development of eye-hand coordination with Peter's. The picture demonstrates that the overall effect shows a serious lag between the infant and normal children in eye-hand coordination. His development at one year is equivalent to 18 months.

In contrast to the lag in postural development between Peter and normal children, there is a picture of normal development in eye-hand coordination. (The center line indicates the normal postural development curve in the graph below.) During his first 8 months of life, the spread from the lowest to highest achievements on each examination was

FIG. 1
COMPARISON BETWEEN POSTURAL-LOCOMOTOR DEVELOPMENT
OF SCHIZOPHRENIC CHILD (PETER) AND CONTROLS

3 to 4 months. This disorganization is comparable to a 6 year old child whose achievements range from a 1 or 2 year level, up to the 5 year level. We are familiar with this lack of integration between different functions in the psychologic performance of older schizophrenic children and in schizophrenic adults. The same disorganization was observed in the neurological development of this infant from one month of age.

The last deviation in this infant's biological development to be discussed here is the correlation between Peter's abnormal neurological development and a number of physiological disturbances.

Figure 4 shows again Peter's uneven postural development. The vertical line at 10 months indicates the age when posture lagged the most, which was followed by the rapid return to normal. It can be seen that

body growth, and growth in head circumference began to lag shortly after postural tone did so. The rate of physical growth reached its lowest point also at 10 months, and accelerated after that, paralleling the course of neurological maturation.

Autonomic disturbances coincided with the lag in physical and neurological development. The vasomotor disturbances during this period included pallor, cyanosis and mottling of peripheral origin, and dermatographia, which were worst during the period of greatest lag in growth. Gastrointestinal disturbances included spastic constipation, and both increased and decreased appetite. For the first 5 months of life, even while growth was slowing down, Peter ate voraciously. At his lowest point, at 10 months, he gave no outward signs of being hungry, although he ate well when

FIG. 2

CONTRAST BETWEEN ABNORMAL POSTURAL-LOCOMOTOR DEVELOPMENT AND NORMAL FINE COORDINATION OF SCHIZOPHRENIC CHILD (PETER)

fed. At this time he became unable to suck and had to be fed milk with a spoon. The period of torpor and inactivity has already been described.

Interestingly, Peter began to have a series of respiratory and ear infections just after body growth and motor development began to return to normal, during a period when he appeared to be more vigorous and in better physical shape.

The authors' earlier papers have discussed how Peter's physical symptoms evolved into his later perceptual and psychological disturbances, and how the inadequate mothering he received exaggerated both his physical handicaps and his later personality disorganization.

CONCLUSION

The longitudinal observations made on this child, who is clinically schizophrenic at 5½ years, show that the normal progress of neurological and physiological maturation

was disrupted as early as 1 month of age. Biological development differed significantly from the other infants known to the author from means of growth and development processes established in hundreds of children by Gosell and others and from the usual forms of retarded or precocious development.

The following deviations were observed:

1. The presence of an abnormal torpid state in the first months of life. 2. A severe but transient lag and disorganization in postural locomotor development. 3. Physiological disturbances which paralleled the transient neurological disturbances, including retarded physical growth and autonomic instability. These biological manifestations antedated the anxiety and psychological symptoms and appeared to be intimately related to the later clinical manifestations of schizophrenia.

A preliminary study such as this raises more questions than it answers. We plan

FIG. 3

COMPARISON BETWEEN SPREAD OF ACHIEVEMENTS IN POSTURAL CONTROL OF SCHIZOPHRENIC CHILD (PETER) AND CONTROL INFANT

to study a much larger number of infants to determine the critical limits beyond which erratic development may be the first sign of schizophrenia, as distinguished from the spectrum of relatively benign individual variations; and to study how different patterns of maternal care and early physiological support can modify this development.

The capacity of different individuals to maintain psychological integrity in the face of stress is often attributed to elusive qualities we summarize as ego strength. It would appear that there is a related variation in the capacity for integration in the early neurophysiological development of infants. Differences in the growing organization of alertness and muscle tonus, the progression of postural control, physical growth and autonomic stability lend them-

selves to quantitative measurement and analysis. We believe that further study of these individual differences in early neurological integration should increase our understanding of the factors making for mental health and disease.

LEPROSY AND PSYCHOSIS¹

PAUL LOWINGER, M.D.²

Patients at the National Leprosarium in Carville, Louisiana, show a 10% prevalence of psychosis. This prevalence, greatly increased over the frequency in the general population, has implications for a more complete understanding of both leprosy and schizophrenia.

Surveys of the prevalence of psychosis in representative United States communities vary from 5.5 to 12.5 per 1,000 people; schizophrenia occurs from 1.7 to 3.4 times per 1,000 people(1). (Figure 1)

Tuberculosis, a chronic disease similar to leprosy, shows little or no tendency to increase the rate of psychosis in the view of Kraepelin(2), Conlogue(3) and Neyman(4); however, a survey by Forster(5) shows 3 psychotics in 100 hospitalized tuberculosis patients.

Kraepelin(6) states that leprosy does not increase the occurrence of mental illness and refers to Hansen and Moreira to support this view.

Cazenavette(7) in 1927 reviewed the world literature on mental illness associated with leprosy and reported a 3% prevalence of psychosis among leprosy patients at Carville. This survey lacks a system of psychiatric diagnostic nomenclature. A re-interpretation of this detailed investigation using current psychiatric nomenclature is justified and indicates a 9% prevalence of psychosis among the 427 lepers admitted to Carville from 1923 to 1927. (Figure 2)

A census of known mental illness at the leprosarium in September 1953 listed 42 with a psychiatric diagnosis out of the 377 patients. Ten percent of all the patients at Carville were psychotic; 6.6% were schizophrenic. The diagnosis of psychosis included schizophrenic reaction, 25; chron-

ic brain syndrome, 12 (senile 11, cerebral arteriosclerosis 1); and paranoid state, 1. The nonpsychotic conditions included personality disorder, 3; and mental deficiency, 1. (Figure 3)

This census of mental illness was based on the 1950-1953 diagnostic records of the psychiatric consultation service which was reorganized in March 1950 under a Board certified psychiatrist. The entire institutional population was not examined; however, all behavioral and social problems in patients as well as organic and functional disease of the central nervous system were referred to psychiatry after March 1950. Complete psychiatric examinations were performed; standard nomenclature was used and diagnoses were usually confirmed by two psychiatrists. In addition, about 37 new admissions from 1950 through 1953 were seen in brief psychiatric screening interviews.

A few of the more disturbed psychotic lepers had been segregated for many years. A 20-bed closed psychiatric unit has been filled since it opened in 1954. An unknown number of psychotic patients who did not present medical, psychiatric or social management problems were never referred to psychiatry. Much of the patient population was Spanish speaking while the medical staff was not, so the language barrier may have acted to shield some psychotics.

Most of the schizophrenia was of long standing and the records usually did not reveal whether overt schizophrenic symptoms preceded the admission to Carville for leprosy. Nearly all the schizophrenia was of the chronic type with a thinking disturbance, blunting of affect, apathy and isolation prominent in the clinical picture. Considerable intellectual deficit was present on the psychiatric examination of most of the schizophrenics. This finding is compatible with chronic schizophrenia but may also be related to other factors: the low socio-economic and educational level of most of the patients, the effects of the physical illness and the loss of intellectual stimulation due to the isolation and stagna-

¹ Read at the 114th annual meeting of The American Psychiatric Association, San Francisco, Calif., May 12-16, 1958.

² From the Lafayette Clinic and Wayne State University College of Medicine, Detroit, Mich. These observations were made while the author was a psychiatric consultant at the U. S. Public Health Service Hospital (National Leprosarium), Carville, La., 1953-1955.

tion of institutional life. The language barrier of the many patients speaking little or no English was an obstacle in the psychiatric evaluation as well as the socialization of those patients within the institution.

The lack of diagnosed psychoneurotic reactions indicates only a relative infre-

quency of psychoneuroses. The stigma and fear attached to psychiatric referral, the unavailability of psychotherapy, as well as the reduction of anxiety by religion, work assignments and general medical management kept psychoneurotics from the psychiatrist. The absence of manic-depressive

FIGURE 1
PERCENT OF PREVALENCE OF PSYCHOSIS AND SCHIZOPHRENIA FOR POPULATION OF UNITED STATES COMPARED TO PREVALENCE AMONG LEPERS AT CARVILLE

FIGURE 2
PER CENT OF PREVALENCE OF PSYCHOSIS AMONG 427 LEPERS ADMITTED TO CARVILLE 1923-1927, BASED ON PAPER BY CAZENAVETTE

and involuntional reactions appears to be valid. The author's contacts with patients from 1953 to 1955 confirmed the rarity of manic-depressive and involuntional reactions as well as the reduction in the usual frequency of psychoneurosis.

Psychological and social factors in the Carville patients explain many of the psychotic reactions. The patient population is largely from a low socio-economic segment of the population of 5 states : New York, California, Texas, Louisiana and Florida. Leprosy is seen by many patients as lifelong exile from community, family and friends. The social stigma of leprosy is overwhelming both in fact and fantasy. Admission to Carville is often followed by a depression of mood lasting two or three months. Denial of leprosy among patients may occur on admission or during the course of institutional care. Withdrawal, guilt and the loss of self esteem due to the onus of leprosy may result in depersonalization. The common sight of a few patients without eyes, noses, ears, hands or feet due to leprosy may correspond to a psychological disturbance of body image. The emotional atmosphere of the better adjusted patients of the institution is one of passive-depend-

ent resignation with many paranoid overtones. Hope and gaiety are largely lacking. Many patients stay for their lifetime and lose all family interest and ties. A few leave without permission but most of these return voluntarily. Some patients who are considered cured are unwilling to leave because they have no place to go(10).

A program for the exploration of this problem can be formulated. The atmosphere of the leprosarium in terms of its psychosocial impact on the individual leper should be evaluated. This would require knowledge of the institutional atmosphere as well as consideration of personality types common to the patient group. Recognition of the patient subgroups based on racial, religious, language and other cultural identities is necessary, *e.g.*, the patients whose blindness is due to leprosy who live together in a "blind house," small groups of Negro and Chinese patients segregated by residence hall, the few well-educated patients of Northern European descent who are missionaries. The long-standing social barriers between patients and employees are significant. Recent successful patient activity to oust an unpopular Medical Officer in Charge is one of the few examples of

FIGURE 3
PER CENT OF PREVALENCE OF MENTAL ILLNESSES AMONG
LEPERS AT CARVILLE IN 1953

patient group integration(8, 9, 10).

Psychodynamic studies of the individual patient by means of projective techniques as well as psychotherapy should be a part of the program to understand the reaction of the total personality to leprosy. Some of the psychotic reactions as well as the behavioral and neurotic problems would be best understood by this approach to the patient.

The impact of the psyche on the leprosy process in terms of etiology, course, complications and prognosis could be studied at Carville. Leprologists have suggested that the patient's emotions play a significant role in the course and cure of leprosy(11, 12, 13, 14) as well as in the complicating allergic lepra reaction(15). It is reported that hypnosis has been used in the treatment of the depression, pain and paresthesias of leprosy in Russia with some success(16). Leprosy remains a disease with many unknown etiological factors. There are definite resemblances to Selye's diseases of adaptation(17, 18, 19, 20, 21). We know the brain-pituitary-adrenal relationship is involved in these diseases of adaptation. The complexity of the mind-body relationship in leprosy invites a vigorous, multidimensional study.

A biological affinity of schizophrenia for lepers could explain an increase of schizophrenia among them. The incidence of schizophrenia and psychosis in chronic hospitalized leprosy patients should be compared to that of first admissions as well as non-hospitalized lepers; tuberculoid and lepromatous leprosy patients may differ in type and rate of mental illness. Lepers in Asia and Africa may show a different frequency and form of psychosis from those in the United States. Both leprosy and schizophrenia may have important constitutional determinants and there might be some common factors. The significant role of bacterial, infectious, hereditary, environmental, resistance, immunological, allergic and racial factors in the etiology of leprosy suggests that some of these dimensions might be used to approach the schizophrenia-leprosy problem.

Leprosy may cause an organic, metabolic or toxic lesion of the brain. The literature on leprosy(22, 23, 24, 25, 26), including

recent autopsy studies on Carville patients(27), largely concludes that no demonstrable organic pathology of the central nervous system is associated with leprosy. However, the neurology text by Baker 28 and Serejski's 1926 case report 29 emphasize the high incidence of psychosis in lepers and the possibility of an organic brain disease associated with leprosy.

The problem of central nervous system dysfunction in leprosy should be reexplored by a program including complete neurological and psychiatric examination, cerebral fluid studies, electroencephalograms and psychological tests. This clinical evaluation of the psychotic leper should discriminate between a schizophrenic and an organic psychosis. A control group of non-psychotic lepers studied in terms of central nervous system function may be necessary. Further examination of post-mortem material may be indicated.

There are an estimated five million persons afflicted with leprosy in the world(30). "Leprosy in the United States is a definite, though not a great, public health problem," according to a 1955 survey by Badger(31). A comprehensive study of the mentally ill lepers at the U. S. Public Health Service Hospital at Carville would fill the manifest need for clinical data in order to plan psychiatric care for lepers. It would also be of genuine value in clarifying the psychophysiological aspects of leprosy.

SUMMARY

Leprosy is a unique stress with anatomic, physiologic, psychologic and social effects on the individual. Here is an opportunity to explore this stress in terms of the mental reaction. We would expect to learn much about causation of schizophrenia and psychosis in the Carville patients. Such a study also offers hope of a better understanding of the role of psychological and social factors in the origin of all schizophrenia.

SOME PSYCHOANALYTIC IDEAS APPLIED TO ELATION AND DEPRESSION¹

BERTRAM D. LEWIN, M.D.²

Those of you who examined the photocopy of Freud's manuscript of *Hemmung, Symptom und Angst* which was exhibited two years ago in Chicago may have noted that he emended the title. Before writing the essay, Freud appears originally to have set down the words *Hemmung und Symptom*, then later to have added the word *Angst*, transposing the *und* by means of a loop, so that it came between *Symptom* and *Angst*. This small alteration serves to indicate that during the writing, the topic of anxiety came to have equal importance with inhibition and symptom. Freud's correction was the first that the title received. The second, so far as the English translation is concerned, was made in America. Two translations were published, one in England, where it kept the literal translation of the German title, *Inhibition, Symptoms and Anxiety*. The American version omitted the words *inhibition* and *symptom*; and it bears the title, *The Problem of Anxiety*. The new name did not originate with the American translator, the late Henry Alden Bunker, but with the publisher, Mr. W. W. Norton.

These emendations have their meaning. They herald the book's effect on the thinking of the psychoanalytic world. For, looking back on the thinking and discussion which the book has provoked, we can see that its main topic is anxiety, and that along with the concept of defense this topic has received most of the attention of its readers. We can thus appreciate better the point implicit in Mr. Norton's editorial decision, for this able editor seems to have sensed prophetically the central interest of the book. Of the three nouns that make up its original title, inhibition is spoken of most rarely. Symptom, too, if one understands the argument of the book, is no longer an

elementary, prime concept, as it once was. A symptom, in the context of this book, is something not elemental, but compounded of ingredients. It is what we have come to call a structure. Into this structure go instinct and defense against instinct, and if we were to rename the book to-day, the title chosen might well be *Instinct, Defenses and Anxiety*.

These are certainly the three concepts that we apply in our dealings with such facts as are being discussed at this meeting, facts which through tradition and for convenience of communication we still refer to as symptoms and in particular as symptoms of the affective disorders. At this point we immediately run into semantics and feel the need for precise definitions. For, although we use an old word, symptom, it too, since it cannot be renamed, needs reconsideration. In our modern context, it has come to have a new meaning. When to-day we speak of symptom and apply to it the concepts of instinct, defense and anxiety, the old name is a new idea. We have to eliminate from our memory the implications of its old definition—namely, that of a sign or indication of an underlying disease. In the old sense of a sign, a symptom is an element from which conceptually we build up disease entities or more colloquially, diagnoses. Our present concept, contrariwise, makes of it a complex structure which we can take apart into simpler, antecedent, more elemental parts; and though the word remains, we are far from regarding it as a sign. Semasiology has departed from symptomatology.

That this is true is no longer a novelty. Following the teachings of Adolf Meyer, we have long since tried to abandon the idea of an "underlying disease" as an explanation of what we nevertheless still call a symptom. We know that in the affective disorders, particularly, a disease entity is a most debatable assumption and that the word symptom must be freed of the dust of its past. Our present use of the word has taken us back, in a certain sense, before our

¹ Read at the 114th annual meeting of The American Psychiatric Association, San Francisco, Calif., May 12-16, 1958.

² The American Psychoanalytic Association, Survey of Psychoanalytic Education, 32 East 64th St., New York 21, N. Y.

19th century predecessors, our progress has depended on a sort of regression, and we have recaptured some of the word's original Greek signification. The Greek word *symptoma* meant a mischance, an accident. It came from the verb *sympipto*, to fall together violently, the same verb from which we have derived the word *asymptotic*, applied in geometry to curves which do not fall together, or as we usually say, coincide. According to its etymology, therefore, a symptom was something that one fell in with and then fell together with. It was an event, and for no more than for any other event was there implied a hidden cause. It belonged to nothing; it represented nothing; it was not a sign of something else.

This point of view has been much reiterated in expositions of schizophrenia, and when into discussions of that disorder there is insinuated the 19th century idea of a "disease entity," we are by now on the alert to recognize and repudiate it. We are considerably less alert, however, when we discuss the so-called affective disorders. Here we encounter with some complacency ideas that imply an ideal entity or a causal reality behind the phenomena. True, this *ens* is no longer called the disease process nor is it supposed to have independent existence. But the assumption of such an existence is often present, wrapped up and concealed in an innocent-seeming, new phrase. The phrase is: the underlying depression. This putative underlying depression is then invested with attributes proper to a causal underlying disease process. It is thought of as something behind the manifest facts and granted a causal role.

This mode of thinking comes to our attention often in discussions of hypomania or elation. One hears and reads that beneath every elation there is an underlying depression. Usually the statement is meant to be descriptive. It intends to imply no more than the fact that a depression makes its appearance after some elations have subsided. If this empirical fact were so stated, there would be no difficulty. We should then understand that there were two events—a state of elation and a state of depression—and there would be no tacit statement that one caused the other.

But more often such a tacit causal relation is exactly the implication. Many would reject the idea that they mean to speak of a disease entity, vaguely understood by the phrase in question that two opposite states of mind exist in one person—that there are as if a conscious elation and a concurrent unconscious depression. Such a remark has one of two meanings, depending on whether it refers to the affects of elation and depression; that is, the joy and the sadness; or whether it envisages the psychic structures which go by the same names, and which in the old psychiatry were called symptom-complexes. In either case there is difficulty. The concept of an unconscious affect of depression is not an agreeable one to psychoanalytic theory, which has had trouble enough with the idea of "unconscious anxiety." If the statement refers to an unconscious symptomatic structure, the situation is equally uninviting. We should then be confronted by a strange theoretical situation. There would be two simultaneous formations involving the same parts of the total personality in diametrically contradictory ways. The situation is theoretically inadmissible. For, in the elated symptom the ego would be unified with its superego, while at the same time in its concurrent unconscious depression, the same ego would be completely at odds and separated from the same superego. We should run into a personality structure to which an ordinary "double personality" by comparison would be simple indeed. Conceptually, the easy Copernican system of interacting id, ego and superego would be replaced by a Ptolemaic system of egos involved with ids and superegos in ever more complex topographic cycles and epicycles. The idea of an "underlying depression," at first sight so innocuously simple, would be revealed as extraordinarily complex, as masked in a specious simplicity.

The idea of an underlying depression is equally delusive as an explanation of the instinctual situation. Again it leads to paradox and contradiction. While a triumphant mania is proceeding with all sorts of externalizations of energy, by inference there would be at the same time an underlying inhibition and inward direction of aggres-

sion. Another tacit implication of the phrase is a genetic one. It assumes that a manifest elation, if analyzed and properly interpreted, will be revealed as a present-day reaction against an original, primal, infantile depression. The underlying depression, in this loose usage, is not a present bad situation to which one has a double or two-layered reaction, but let us say a manifest elation covering a repressed original depression. This explanation then rests as it were with an original infantile depression, and not instinct, defense and anxiety as the ultimate genetic basis of the current elation.

Let us return to Freud and *The Problem of Anxiety*, and to the elements he uses in that book to build up a symptom, conceptually speaking. An elation, according to this scheme, is a symptom. Into the symptom of elation enter defenses from the ego that are due to pressures from the id, the superego, and the real environment. The instincts and the defensive measures in the elation are familiar to us and need no repetition beyond the naming: the instincts called oral, the defenses called identification and denial. The active mania in its denying function is a great flight from the dangers threatened by the oral id impulses, and these dangers determine the content of the anxieties that are discovered in the elation. The anxieties are expressed in oral language; they are fears of being eaten, of starving, of being put to sleep (killed), of being separated, and the rest. This picture is not complete, but it indicates what is meant by the formulation of the elated state in terms of the elements of *The Problem of Anxiety*. It relates the psychoanalytic findings (not merely the superficial observations) of the elations to the instincts, to defenses and to anxiety. It involves no reference to a depression, which has its own pattern for handling the oral conflict.

It may be asked, what then is the relation of depression and mania? If one can formulate them separately without taking the other into account, what is it that they have to do with each other? Is it not true that the empirical clinical findings demand a postulation of some sort of relation between them? If then we are asked on the basis of

a theory to give them separate structural, instinctual and genetic consideration, are we not going too far and discarding too many evident facts that show them to be two parts of common clinical pictures, those which determined the names "affective psychoses" and "manic-depressive"? In the interest of maintaining a theory, must we abolish the significance of the hyphen between the two words, *manic* and *depressive*?

The answer obviously is that we cannot abolish the hyphen. We are compelled to state a relationship between the two affective conditions, and in fact such an answer has been made. It states that a mania is a regression, genetically speaking, which goes back to an earlier condition than the regression which characterizes the depression. The ego in mania is not denying a depression; it is denying death and the fear of dying by a declaration of invulnerability and immortality. The false happiness is a statement of world-mastery such as was enjoyed by the earliest "pleasure-ego" before the establishment of the reality principle.

According to this formulation, the hyphen does not mean *because of*. It does not mean: because of depression, therefore mania; nor alternatively, because of mania, therefore depression. Under the Kraepelinian regime, it did not have this meaning either. Then it simply meant *and*: mania and depression were two aspects of the presumptive underlying disease process. To us, the hyphen cannot have this implication, and the best interpretation is surely *or*. Mania *or* depression, we say, may arise or may be formed according to the particular regressive defenses selected by the ego to meet the inner conflict between instinct, superego, and reality.

A great deal more can be said on the score of this regression, and indeed a great deal has been said in the literature of the past few years, which it would be distracting to review at this point. Here I think it would be more appropriate to clarify the relation between the elation and the depression, as well as to explain the *or*-hyphen relationship by a procedure which has often demonstrated its value. I mean that we seek for clarity by turning to the study of

dreams. In this context, the analogue of the elated state is what Freud has called the "happy dream."

For example, the dreamer visited a dying friend the day before the dream. He dreamed of his sick friend, in "the pink of health," stalking through the room, dressed in evening clothes, his face aglow. How wonderful he looked! The dreamer woke up roaring with laughter. All such laughter is macabre—and such dreams too. They deal, Freud stated in *The Interpretation of Dreams*, with thoughts of the dreamer's death. What a store of clinical wisdom is gathered into that book! A dream such as this will clarify the affective details of the elated state. The laughter is meant of course to divert attention from the fear of death; and roughly, this is what an elation is for. In such a dream there is no underlying depression; there is an "underlying" and distortedly manifest fear of dying. The laughter does not serve as a screen to cover "depression." It is a pre-mourning, pre-melancholia laugh: "Ha ha! He will die, not me!" The laughter is a "screen-affect"; but the other affect that it masks and supplants is anxiety. The dream-work takes the sleeper back to a period in which he knew no death. The screening is a regression to a time when the idea of dying had not arisen, certainly not in connection with one's self.

This brings up the topic of screen-affects, a phrase for which I am afraid I am partly responsible. This phrase has been understood again to mean that a happy mood may exist superimposed over a concurrent, or latent, depressive one. This is not what I meant when I introduced these words, which I used by analogy with "screen memory." I specifically referred in my original discussion (in *The Psychoanalysis of Elation*) to the regressive aspects of screen memories, and I suggested that the affect which arose whether in dreams, in free association on the couch, or in the elated states, might be displaced in time. It was thus intended to point to the latent content, and shared with the concept of screen memory the quality of referring to a different "real" occasion. I now think I might have referred more simply to a "displacement in time," but in my original ex-

position I was concerned not only with the screening function of the mood but also with the sense of reality. For an explanation of both I utilized appropriate discussions in *The Interpretation of Dreams*.

Looking back on the development of the psychoanalytic theory of the depressions and elations with the purpose of finding out why so alien a concept as the "underlying depression" can still affect us, we come upon the idea that this underlying depression may be a somewhat altered version of what Abraham called the "primal depression," or the infantile prototype of a "melancholic depression." In Abraham's famous case, the recurrent depressions were found to be repetitions of the patient's frame of mind after he had witnessed involuntarily the coitus of his parents. Melanie Klein has expanded and modified the idea of the infantile prototype and has postulated a "depressive position" in infantile development, which is then followed by a "defensive manic position." Abraham too went further in his formulations and suggested that manic attacks without preceding depressions in adult life might be sequels of infantile depression, the belated tail-end, as it were, of a manic-depressive sequence. Abraham was cautious, however, in putting forward this proposition and stated that he had no clinical material to bear him out.

In my opinion, both Abraham and Klein have put the cart before the horse genetically when they see mania as an after-effect of depression, whether as the running of a course or as an ensuing defensive reaction. My alternate assumption is that in infantile development the prototype of elation, which would be oral satiety and union at the breast (Rado), precedes any infantile or adult depressive manifestations. I trust that this point of view was made sufficiently clear in my previous writings.

Another use to which the idea of an underlying depression has been put is in the explanation of some types of delinquency. The idea has been propounded that the delinquent of this particular type engages in asocial actions to take flight from an underlying depression. As a very special, partial and isolated working idea, this point has apparently been of value. I have had

no therapeutic experience with the age group about which such statements are usually made, but I have been fortunate enough to hear case presentations at conferences in the psychoanalytic institutes. In such cases, it seems to me, the idea of an underlying depression may have been introduced because the patient's behavior was of the hypomanic, driven sort; but in the same cases, the acting out seemed to mask not depression but fears of dying and impulses to die. From my present standpoint, a formulation in terms of the psychoanalytic theories of the affective states—that is, in terms of instinct, defense, and anxiety—would in the end be more fruitful and more consistent than one which depended on the concept of an underlying depression. It should not be difficult to make the necessary conceptual corrections.

If we were discussing other disorders than the affective psychoses, we should all be clearer concerning our basic concepts. Since the writings of Bleuler and Adolf Meyer, this is certainly true for schizophrenia. And if we took the same attitude towards the affective states that we do towards the neuroses, we should also free ourselves from the dust of the 19th century. For example, a patient entered the psychiatric ward unable to speak, stand or walk; the diagnosis was conversion hysteria, aphonia, astasia-abasia. After some therapeutic handling she spoke, stood and walked. She no longer had a conversion hysteria. But she was obsessed with various unpleasant thoughts and she found herself forced to count such items as the cracks in the furniture, the pleats in the curtains and the like.

I saw the patient in question some 35 years ago. Already psychiatry was too sophisticated to think that anything was accomplished by a change in the "diagnosis." The simple statement was made that after the hysteria cleared up, the patient developed an obsessional-compulsive condition. Neither underlay the other, nor did one cause the other. To this statement of the case, we need only add that one set of defenses superseded another, that a new regression had been made, and that in consequence new symptoms based on different instincts and defenses made their appear-

ance. This would coincide with Freud's concept of the etiology of the obsessional neurosis.

In a comparable matter, if we accept Abraham's finding that between depressive attacks patients often show obsessional symptoms (and one might add that others are phobic and still others beset by somatic, mild conversion symptoms), we still need not think of such symptoms as "warding off a depression." They could be conceived as different ways of meeting an inner conflict at different levels of regression and with different defenses. A psychoanalytically conceived person, the psychoanalytic "model," calls into activity various defenses and meets the instincts at various levels of regression. He, or "it," does not carry about within a formed underlying mania, a formed underlying hysteria or obsessional neurosis. We cannot logically reify the "possibility" or "potentiality," diathesis or what-not, for forming them. The elements of the psychoanalytic model are the instincts and ego functions, and the topography of psychoanalytic man is the id, ego and superego.

Hence and finally, I should like to propose caution in the use of another familiar idea taken from the older psychiatry; namely, the depressive equivalent. As this term is employed, it suggests that an anticipated depression has not appeared but instead a given set of somatic or other symptoms. For description there may be no harm in the term, but as a basic concept it shares some of the disadvantages outlined in discussing the concept of the underlying depression, and it threatens to confuse our ideas of etiology by introducing alien frames of reference.

SUMMARY

Looking back over this exposition, I see that from first to last I have been overtly or tacitly concerned with the meaning of words, which some may think an unimportant matter. I should disagree with any such opinion. When Freud explained what he meant by the statement, "The hysteric suffers from reminiscences," he chose an allegory that depended on philology. A hysteric, he explained, was like a modern Englishman who wept every time he passed

Charing Cross, etymologically *where the cross*, so named because at this spot the funeral procession of Queen Eleanor stopped on its way from London to Westminster in the year 1204 and a cross was erected to mark the halt.

Let us not suffer from reminiscences. Even if we transiently must accept the vocabulary of our ancestors and if we speak

of manic-depressive states, of depressions, or of depressions, let us at least be aware that we are in the 20th century, that time separates us from the burial of the dear Queen and from the originators of the old terminology. A quiet tea may be in order, but it should not blind us to the busy modern traffic.

THERAPEUTIC FACTORS IN ALCOHOLICS ANONYMOUS¹

HERBERT S. RIPLEY, M. D. AND JOAN K. JACKSON, Ph.D.²

Alcoholics Anonymous has been in existence since 1936. Even in the absence of statistics on recovery rates, it is known that many benefit from association with Alcoholics Anonymous. Yet there have been few attempts to analyze the treatment process in order to specify its therapeutic ingredients. Simmel(3) interprets the essential therapeutic factor of A.A. as a reinforcement of the superego through prohibition and a spiritual experience which acts to undo wrongs and resolve guilt. Stewart(4) emphasizes fellowship with empathy and the acknowledgement of a greater power. Hayman(2) points out that with therapy the patient will discover the power of choice and will choose not to be an alcoholic. This is in keeping with Freud's formulation that the aim of psychoanalysis is to give the patient the ability to choose one way rather than another(1). Trice(5) discusses the significance, the readiness and the capacity to affiliate with A.A.

On the surface, Alcoholics Anonymous is a federation of autonomous but loosely organized groups of alcoholics who are learning to live without alcohol. The members believe that sobriety can be achieved and maintained by associating with one another, by sharing their common problems, by trying to help other alcoholics to recover and by following a program called "The Twelve Suggested Steps."

The Twelve Steps are a series of statements which purport to describe what successful members have had to do to remain sober. The Steps are considered as guideposts for the alcoholic to reorganize his life. The content of these Steps can be summarized briefly: 1. Accepting oneself

as an alcoholic, *i.e.*, as unable to drink in a controlled fashion because of physiological and emotional pathology; 2. Being willing to change one's personality, relationships and way of life in a manner conducive to healthier adjustment; 3. Accepting spiritual help from a self-defined God and His guidance in day to day living; 4. Taking an honest and continuing "personal inventory," *i.e.*, an assessment of one's self and of one's relationships; 5. Taking action to change dysfunctional personality attributes and behavior as they are recognized; and 6. Helping other alcoholics to recover.

There are also the "Twelve Traditions," a series of rules governing the behavior of A.A. groups and of individuals as A.A. members in relation to outsiders. The Traditions make it clear that A.A. permits the achievement of only one goal, that of directly helping the individual to maintain his own sobriety. They specify that A.A. will not get involved in any other type of activity and that members will use A.A. solely for achieving and maintaining sobriety.

Other explicit elements of the A.A. program include being honest with oneself and others, attempting only what is possible and thinking through all problems before taking action. In addition, A.A. members are expected to place sobriety ahead of all other goals and relationships because without sobriety, nothing is achievable.

When A.A. is observed in operation over a period of time, it becomes apparent that there are many therapeutic aspects which do not appear on the surface and which are never made explicit by members. The organization's structure and functioning have evolved to the point where they provide a consistent, integrated therapeutic milieu which is tailored to the treatment needs of alcoholics. It provides forms of emergency psychiatric care, group psychotherapy and individual psychotherapy. A.A. makes use of the active alcoholic's patterns of behavior, relationships, thought processes and orientation to life. It retains these but

We wish to acknowledge the helpful cooperation of the organization and of individual members of Alcoholics Anonymous in carrying out this study.

manipulates them toward the goal of sobriety.

This overall plan for dealing with the problems of the alcoholic does not preclude the use of social agency or professional help. For example, some members are encouraged to seek help from professional psychotherapists. In turn, psychiatrists may refer alcoholic patients to A.A. (2) because they feel that A.A. membership may supplement or complement the work of the therapist.

A.A. uses emergency treatment methods extensively and in a manner very similar to traditional emergency psychiatric care. The organization accepts the fact that alcoholics feel rejected if their needs are not met immediately. It provides emergency attention whenever it is called upon to do so. Being a large group, it can meet these needs in a way that would be impossible for individual psychiatrists. Whereas a person seeking psychiatric help would make an appointment to see a psychiatrist, the candidate for A.A. is seen immediately on demand. He will receive just as prompt a response the twelfth time he asks for help as he did the first time. A psychiatrist would consider it undesirable to be routed out of bed at two o'clock in the morning but A.A. expects this. A.A. believes that it is only common sense for the new member to call his sponsor whenever he is needed, regardless of the hour. In most large cities the candidate can attend an A.A. meeting at almost any hour of the day or night or can become involved in an impromptu meeting at one of the many clubs. This is in contrast to usual group therapy experience, which occurs only at scheduled intervals.

The majority of A.A. members entered the organization as a result of a decision made when aid was sought in an emergency. When an alcoholic first seeks help from A.A., he is usually trying to sober up after a long "bender." His self-esteem is at a low ebb. He feels guilty, ashamed, depressed, anxious, tremulous and helpless. As a rule this is only one of numerous periods during which he has felt desperate and has been willing, temporarily, to consider the possibility of change. As in these earlier periods, he is ambivalent about changing and about accepting help. He mobilizes

his resistances but at the same time calls A.A. on the off-chance that they offer a way out.

The initial contact with A.A. is similar in principle to the initial interview of any psychiatric patient but different in some of its mechanics. A.A. recognizes that a crisis exists and sends out two of its members immediately, before the alcoholic has had a chance to rebuild his defenses. The emergency team devotes its energies to establishing rapport, to providing emotional support, to helping the new client to define the nature and extent of the problem and to helping him decide on a course of action once the alternatives are clear to him. The atmosphere is permissive, accepting and unemotional. The means used are the personal stories of the A.A. callers, which include statements about their own ambivalences at the outset of membership and how these were resolved. The client is told enough to permit him to accept his callers as alcoholics whose problems were equivalent to his own at one time. He can identify with them. He is told enough about their alcoholic behavior that he can feel that his own actions are not particularly unique, reprehensible or hopeless. He is given an opportunity to discuss his problems, his doubts and his resistances in a matter-of-fact atmosphere. His callers agree with him that a problem exists. They avoid being drawn into his feelings about himself, his rationalizations, or his searching for causes. Their attitude is rather that a problem exists whether or not the rationalizations and putative causes are valid. The relevant question is, "What are you going to do about the problem now?" The two callers outline the way A.A. operated in their experiences. They discuss the alternatives to A.A. They make it clear that he is free to try the alternatives if he chooses, but they convey a lack of optimism about all "will power," "control of drinking" and magic pill methods.

At the end of the visit, the alcoholic is left with information on how to reestablish contact with his callers if this should be his decision. He is told that he alone can decide what to do, that he alone can do it, that the recovery process is long, often painful, and will involve extremely hard work,

but that if he is well motivated it can succeed. The obvious fact that his callers have been sober and became sober in A.A. serves as a powerful inducement to try the A.A. program.

The sponsor-new member relationship most closely approximates the psychiatrist-patient relationship. Usually the new member selects as his sponsor one of the two members who made the emergency call. The sponsor serves to bridge the gap between the isolation of alcoholism and full membership in A.A.

This is the closest relationship A.A. has to offer. It is potentially the most conflict-engendering relationship. However, the organization has structured the relationship so as to minimize difficulties. The sponsor undertakes this relationship voluntarily because he believes that the effort to help another alcoholic ensures his own sobriety, whether or not the effort succeeds. He plays the role of the older, experienced male who can provide emotional support, understanding and guidance. He helps the new member to clarify his own thinking and to persist toward his goal of sobriety. The new member has no obligation toward him and can terminate the relationship at will. The initiate chooses his sponsor, and it is quite within the expectations of the organization that a man will have several sponsors before he himself undertakes the sponsorship role.

At first the sponsor meets all demands which fall within A.A.'s scope. A.A. will help the alcoholic think through any problems but will not solve them for him or make any attempt to change circumstances for him. It emphasizes that circumstances were not relevant to excessive drinking and they are no more relevant to sobriety. Gradually the sponsor shifts the alcoholic's problems to the group for their resolution or analysis.

In this interaction the new member has an opportunity to work out some of his problems with close relationships. The sponsor engenders admiration and becomes a figure for identification. He is chosen because of his ability to communicate his experiences meaningfully to the new member and because he can help him to work his problems through, to make decisions

and to take action on the decisions. Yet the sponsor makes no demands. His own needs are met through helping another alcoholic who has chosen him and because his prestige in his group is enhanced. In this milieu, the initiate is able to see many of his interpersonal difficulties in a new light. When the new member in his turn becomes a sponsor, he has an opportunity to work out even more of these problems.

Group therapy in A.A. takes many forms. The major types of group meetings are: 1. those open to the general public; 2. those open to select non-alcoholics; 3. closed meetings for members of A.A. only; and 4. study group meetings. A.A. considers its group activities to be the major therapeutic instrument. The group acts as a kind of family which helps the "baby," as the new member is often called, to learn how to live a normal life, to form healthy relationships with others and to arrive at a more realistic and satisfying self-conception.

Most members begin by visiting all the types of groups until they find one in which they feel at home. Groups cannot refuse to accept a member, nor can they ask one who is uncongenial or disruptive to leave the group. However, it is regarded as common sense that any member who feels uncomfortable in any group will leave it and look for one which is more congenial.

The feelings which members express about the group they select as their own are those which usually refer to families. This home group tends to be more permissive than most families. There is no formal authority structure, the only authority being derived from prestige due to maintained sobriety and the ability to help others to resolve their problems. These home groups tend to be cohesive and loyal, which diminishes anxiety and enhances self-esteem. The suggestive effect of the implantation of the theories of the group can be a potent therapeutic force.

The meetings of these home groups are usually open only to A.A. members. As a rule the members are seated informally around a table. They often drink coffee or soft drinks throughout the meeting. All problems are discussed as openly and honestly as possible. The group earnestly attempts to formulate the problem in a man-

ner which permits resolution. There are no tabooed subjects and none which is considered insignificant or overwhelming. Members think of the groups as problem-solving groups, and the emphasis remains on the aspects of the problem which are relevant to its solution. Gradually the new member incorporates the A.A. norms and patterns of thought about problems. Through the sharing of his conflicts, the burden of guilt is attenuated by being partly shifted to the group.

Study Group meetings are designed primarily for the new member. Those attending sit at 12 tables, one for each of the 12 steps. The new member can sit at any table he wishes and stay at that table until he feels he has thoroughly worked through the problems associated with it. Senior members attend and act as informal group leaders or as consultants. The Study Group provides the new member with an opportunity to study the program of A.A. systematically. It also provides a home base until the member has selected a home group and until his relationship with his sponsor becomes stabilized.

Open meetings, *i.e.*, those which the public can attend, are primarily for information and education. Speakers follow a set formula in their talks, conveying enough about their alcoholic lives to permit them to be identified as alcoholics, enough about the situation which brought them to A.A. to permit identification by any potential new member in the audience and enough about what happened to them in A.A. and how they feel now to indicate that they are en route to recovery. The talks also indicate that alcoholism can be accepted and that the past can be integrated into the present comfortably. Open meetings provide a milieu within which an alcoholic can make his first contact without in any way committing himself.

Coffee is served after all meetings. The groups break up into smaller groups where discussions continue, often at an even more intense and personal level than before. The setting is the familiar one of sitting around a table talking with alcoholics over a drink, but the content of the drink and of the talk has changed. The emphasis has been altered from a drink-centered situation to a

people-and-relation-ship centered one. The bemoaning problems to attempting to deal effectively with them. The emphasis is on assets and their utilization. Personal shortcomings and environmental liabilities are minimized.

A.A. has retained some aspects of the alcoholic's ways of relating to people, modes of life and thought processes and has channeled these toward the new goal of sobriety. The program and the group activities provide a consistent and integrated milieu. There is agreement on the nature of the illness of alcoholism. Anyone who disagrees is invited to go out and drink and prove the A.A. definition of alcoholism to be wrong. Alcoholism is thought to be a physiological "allergy" coupled with severe emotional problems. Although the use of the term "allergy" is not the conventional medical one, it implies a deep-seated difference of a physiologic or characterologic nature. This concept serves to alleviate guilt over the condition in which the alcoholic finds himself by explaining it in part on a basis over which he has no control.

The problem then is to work through the self-deceptions which permit a person to trick himself into believing that he can drink in a normal fashion. Some of the elements of his emotional problems are defined as dishonesty with himself and others, the conviction of omnipotence, impulsivity, guilt and shame, inability to enter into relationships which are mutually rewarding and obligating, making excessive demands, projecting blame to the environment and circumstances, manipulation of others, anxiety, depression, fear and perfectionism.

The milieu is structured so that the problems of the alcoholic are made apparent even to him. No demands are made on the individual. He is left in command of his decisions, his choice of groups, the degree of his participation and the extent to which he will accept responsibility for the welfare of the group. The organization has explicit ways of resolving anxiety, guilt, insecurities and fear. It is permissive, cliché-filled and religiously oriented, and relies on implicit social pressures to bring about conformity. It rewards acceptable behavior rather than punishing the unacceptable. It substitutes the satisfactions of warm, ac-

cepting and rewarding interpersonal relationships for the satisfactions and isolations of the bottle. A.A. avoids mobilizing the defenses alcoholics have built up against efforts to legislate their behavior, which in the past served only to increase their identification with other alcoholics and their commitment to an alcoholic way of life. Informal pressures for acceptable behavior become compelling as the alcoholic becomes integrated into a group with which he identifies strongly and whose members agree on all the major dimensions of his problem and its resolution. The alcoholic begins by emulating the behavior of now-sober alcoholics because he believes that therein lies the key to his own sobriety. Later he incorporates the new standards because they have brought not only sobriety but emotional rewards.

In A.A. the alcoholic does not meet such barriers to recovery as his mistrust of non-drinkers and moderate drinkers, his feelings of inferiority in relation to them, his convictions that they cannot understand him, his inability to communicate with them and the very precarious nature of his relationships with them. In contrast, the non-drinkers in A.A. are alcoholics like himself and by definition, understanding and equal. He has communicated only with alcoholics for years and this holds no terrors, especially when the settings, the terminology and the manner in which communications take place are those to which he was accustomed as an active alcoholic. Whereas previous attempts to communicate feelings to non-alcoholics, including physicians, have been impeded by the necessity of clarifying vocabulary and explaining situations, group attitudes, behavior and reactions, these now are taken as understood and communication can flow smoothly beyond this.

Another barrier to recovery has been the idealization of drinking after a period of sobriety. One of the ways in which A.A. combats this tendency can be used as an example of the way in which this organization combats other "typically alcoholic" difficulties. When an alcoholic calls for help, two members make what is called a "Twelfth Step Call." These men have been sober for a minimum of 6 months to a year,

one of them usually much longer. Calling on the new candidate, they are able to see themselves as they were. To communicate effectively with him, they must relive their own feelings when they called for help and their own experiences in A.A. In stressing to the new man that he has a choice about his way of life, they renew their own choice. Alcoholism is turned into an asset instead of remaining a source of shame and guilt. Without having been alcoholics, they could not be helping another alcoholic to recover. These calls are prescribed for the man who feels that his own sobriety is wavering.

Space does not permit an extensive analysis of the therapeutic aspects of Alcoholics Anonymous. However, anyone who observes A.A. in operation over a period will note that many of the concepts and techniques used in contemporary psychotherapies are also used by A. A. These are not conceptualized and they are not used rationally and self-consciously. They have been adapted to the treatment demands of the specific illness which they are intended to alleviate. Among these techniques used are free expression or ventilation of feelings, transference and counter-transference relationships, reassurance and emotional support, explanation and re-education, suggestion and personality analysis with varying degrees of accompanying insight.

Groups are structured so as to permit the release of inhibitions and the free expression of conflicts and feelings. Conflicts can be acted out without threatening the unity and cohesiveness of the group or endangering the new member's relationship to it. Subtle social pressures operate to bring internal conflicts into group discussions. Many emotional needs are met immediately; the satisfactions of others are delayed. Substitutes are provided for some; others are blocked firmly and consistently. The groups place high value on honest and complete expression of feelings and encourage the individual to work out his own standards and patterns of behavior and to develop his own unique sense of identity as a sober person.

In addition to the elements shared with the psychotherapies, A.A. uses alcoholic patterns of thought, relationships and

values and manipulates them toward the new goal of sobriety. Later when the member is healthier it encourages him to change these also. In tailoring a milieu to fit only alcoholics' treatment needs and in serving only one goal, Alcoholics Anonymous is unique.

SUMMARY

The concepts, philosophy and techniques used by Alcoholics Anonymous have been described and discussed. Many of the techniques of individual and group psychotherapy are employed. In addition there is emphasis on the ready availability of emergency attention and the development of permissive, warm and emotionally rewarding relationships with others who have a similar problem.

DISCUSSION

FREDERICK F. BOYES, M. D. (San Francisco, Calif.)—There seems to be general agreement that the success of Alcoholics Anonymous is a modern miracle; however, this should not mean that there is no further room for growth or improvement. Also, since this program is operated by human beings, and often rather sick ones at that, there are bound to be the usual human problems in translating theory and policy into practice. For instance, there are many different ways in which the 12 step caller approaches the person asking for A.A. help. One worker may completely identify with the applicant and may go so far as to supply additional liquor to ease the withdrawal symptoms and help the applicant taper off. Another may take the attitude that the only way to stop is to stop completely and shake it out. There is, of course, every variation between these two extremes.

In spite of the excellent description of the general way in which A.A. functions, this paper gives a too idealized description of what actually goes on. I feel that it is no reflection on A.A. to point out that it is essentially a

group of people, and not a book or a system. Undoubtedly the results would be even better were they able to function as ideally as the paper suggests. Let me illustrate by citing a few subjects where the ideal and actual practice vary. For instance, the 12 step caller is supposedly a person with 6 months to a year of sobriety. All too often this is someone who has just barely recovered, if that, from a drinking bout of his own. Where this is supposed to be helpful in maintaining his own sobriety, it often works in the other direction, with the worker ending up drinking along with the one who originally asked for help. Again it is said that in the group therapy there are no takers. This, of course, is not so. These people share not only the usual popular prejudices but tend to have them to an excessive degree. Therefore, sexual and delinquency problems may be given a very cold reception and result in rejection if anyone has the temerity to press them. Again it is said that repeated calls for help are treated the same way the 12th time as the first time. I am sure that in most cases, after very few such calls, it would be decided that the applicant was not really serious in helping himself and would be told to give much more concrete evidence of his sincerity.

Another impression that needs some correction is that A.A. considers alcoholism to be an "allergy" plus severe emotional problems. Actually most members feel that drinking is the problem and that a few alcoholics may also have emotional problems.

The paper does not touch on the repressive features of A.A. A.A. cautions against any strong expression of emotions; thus they must not resent too much; they must not crave anything too much—except sobriety. Other things that might have been mentioned are the importance of the rescue fantasies in helping the 12th step worker remain sober when this does work for him. The importance of A.A. as a stepping stone to socialization for many patients was quite well covered and the suggestion that the psychiatrist might use the organization for his patients in this way was also suggested.

My main criticism of this paper is that though it lauds Alcoholics Anonymous, a very worthy organization, it does not give very many clues as to what the psychiatrist should do to improve his treatment to the level of A.A. psychotherapy, nor does it indicate what is lacking in the A.A. program itself. Instead this seems to be covered up by comparing Alcoholics Anonymous with conventional psychotherapy, using such psychiatric terms as

"ventilation of feelings", "transference and counter-transference of relationships", "re-assurance", "re-education", suggestion and personality analysis to do so, much of which is not done.

What I think needs to be pointed out is that a sick person can help another sick person, at least up to the degree of his own adjustment. So also can a healthy person help a sick person, at least up to the limit that his

own defenses are threatened, however a person whose adjustment depends considerably on the maladjustment of the sick **person—in this case, the alcoholic can do little to help the sick one and must take a defensively, if not aggressively negative attitude towards him.** This latter group too often involves those who in the alcoholic must deal with in his efforts to get help, and includes doctors, clergy, lawyers, judges, police, employers and families.

CEREBRAL LOCALIZATION: NOT WHERE BUT IN WHOM?

CURTIS PEGHTEL, PH.D. AND JULES H. MASSERMAN, M.D.¹

Man's knowledge of the function of his most developed asset, the brain, is probably less definitive than that of any other organ, due not only to the difficulties in investigating cerebral function, but also to man's reluctance to confront these difficulties frankly.

We plan here to abstract from our long term study² of the effects of brain lesions in animals a few generally ignored but illustrative factors from which certain significant implications may be drawn.

SUMMARY OF EXPERIMENTAL TECHNIQUES

Sixty-four cats and 49 monkeys were studied for 3 to 24 months to determine their individual and social reactions, and their speed, capacity and techniques in solving a variety of problems of discrimination, pattern relations, manipulation and memory. The data were entered daily and graded on 32 scales that reliably measured various patterns of "normal" and deviant behavior on a 6-point range. Thirty-one of the cats and 23 of the monkeys were then exposed at planned irregular intervals to insoluble conflict situations which induced experimental neuroses characterized by manifestations of anxiety and startle, chronic somatic dysfunctions, regressions to earlier behavior patterns, and various other disruptions of individual and social adjustments(1). The animals were allowed to remain neurotic for 2 to 30 months during which their aberrant patterns were

closely studied. After this, they were operated either by open-field or stereotaxic techniques to produce bilateral lesions in the following areas: in cats, the medial dorsal or anterior thalamus or the amygdaloid nuclei; in cats and monkeys, the angular areas 25 or 34 or both and area 13, the lateral or total amygdaloid, or the temporal regions adjacent to the amygdalae; in monkeys only, the equivalent of a Grantham lobotomy. All of the lesions, except those in 12 cats and 7 monkeys, have been confirmed by serial microscopic sections.

SUMMARY OF RESULTS

Despite inevitable variations in site, blood supply and other factors, lesions in the various regions produced specific effects described elsewhere(2). However, the following *generalized behavior changes* could also be observed in *most* of the operated animals: (a) *partial disorganization* of previous learning, including amodulation of neuritic patterns; (b) *diminished adaptability*, leading to impaired problem solving and social adjustments; (c) *"affective" changes*, with lowered startle and withdrawal thresholds; and (d) *increased susceptibility to adaptational conflicts*. The nature, intensity and persistence of these effects were highly dependent on each animal's *pre-operative* training patterns and experiences, and were also significantly influenced by variations in its post-operative treatment. These factors may be briefly reviewed as follows:

Effect of pre-operative experiences As previously reported(2), characteristic traits tended to be preserved or even accentuated by cerebral lesions, i.e., patterns such as excessive caution, dependency or belligerence persisted after any brain surgery. For example, 6 cats and 6 monkeys which had shown deficient exploratory problem-solving, and socializing behavior during 12 to 18 months of neurosis, remained subnormal in these respects for 2 years after lesions in the amygdalae, the frontal lobes or the mediodorsal thalamic nuclei, even though

² Address: Northwestern Univ. Medical School, 303 E. Chicago Ave., Chicago 11, Ill.

³ Thanks are due to these collaborators in our various studies: Louis Aarons, Ph.D., Jacques Cain, M.D., Lawrence Corey, M.A., Paul Favero, D.D.S., Paul Hutt, Ph.D., Robert Johnson, M.D., Arthur Kling, M.D., Melvin Levitt, Ph.D., Thomas McAvoy, B.S., C.E., Gisela Mendel, M.A. and Dino Riccio, M.D.

the animals with amygdaloid lesions became typically hypersexual and the lobotomized ones showed characteristic hyperactivity.

Effect of postoperative treatment. When the operated animals were isolated from laboratory experiences for periods of 4 to 5 weeks, many of them, as previously reported, showed a temporary or permanent impairment of their learned skills and social patterns. We have since found that monkeys—particularly those with lesions in the cingulate areas—which had not shown these effects after short periods of relative inactivity, did so when the imposed inactivity was extended to 10 or 12 weeks. (Fig. 1.) In further illustration of the effects of social setting, it was noted that unoperated monkeys usually confined their quarrels or attacks to specific cagemates or neighbors: in contrast, such hostilities in animals with cerebral lesions, once started, tended

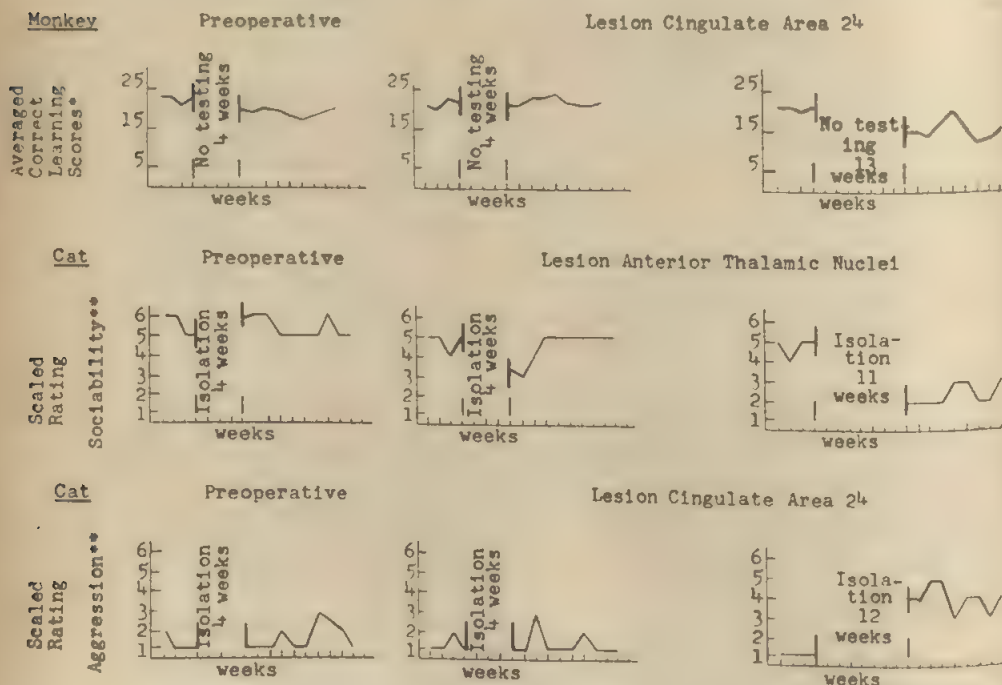

to generalize to many or all other animals in the colony unless the operated animals were paired with only the most congenial or unassailable of partners. (Fig. 2.)

Comparison between neo- and paleo-cortical lesions. In view of certain current theories which hold that "emotions," isolated from the behavior of which they are a part, may largely be mediated by the paleo- and sub-cortical areas of the brain, it is significant that our data on the effects of partial or almost complete lesions of the amygdaloid area and/or adjacent temporal regions with amygdaloid connections indicate that differences between the neo- and paleo-cortical groups are mainly quantitative and not statistically significant.

DISCUSSION

The experimentalist, the clinician, and more recently, the "psychopharmacologist" (3), have too often been exclusively con-

Figure 1. Effects of Successive Periods of Relative Isolation on the Learning Scores and Sociability or Aggression Ratings for Cats and Monkeys

- * Learning scores represent performance on "oddy", a test which requires pattern recognition.
- ** These ratings made from detailed model scale. Higher ratings represent increased Sociability with other cats and increased inter-cat aggression.

connected with the "specific" actions of various drugs or cerebral lesions and have tended to disregard the possibility that the ensuing effects likewise depend on the unique physiological, psychological and experiential background of each subject. Unfortunately, this tendency can result in misleading oversimplifications; for example, Hebb (4) has shown that **some of our concepts of frontal lobe functions have been derived not so much from experimental data as from our yearning after facile theories and systematizations.** And yet, even in the laboratory not only minor variations in anatomy and surgical technique but **even more subtle differences in (a) the constitution and experiences of each animal and (b) its necessarily different handling by and interaction with each experimenter** may greatly alter the results. To analyze, weigh and reassemble these factors takes thoroughness, thought and time, but without these no premise can be truly tested.

Otherwise, comprehensive, though necessarily based largely on special studies, the use of selected data, or on inadequately analyzed inferential procedures.

SUMMARY

The individual and group reactions, learning techniques and capacities, and neurotic and drug influenced behavior patterns of 64 cats and 49 monkeys were studied from 30 to 75 months before and after the implantation of lesions in 10 neocortical and sub-cortical brain areas. The data suggest that:

1. There are effects specific to each lesion despite inevitable variation in site, altered blood supply, etc.
2. There are a number of general changes common to lesions in several different areas.
3. The effects of any lesion are highly relatable to pre-operative characteristics and acquired patterns of behavior.

Figure 2. Frequency of Inter-animal Aggressions after Cerebral Lesions for Two Monkeys

* At no time did we have uncongenial animals living together for more than a few days. Preoperatively this brief interval made no difference in inter-animal aggressions, in contrast to the postoperative data presented here.

4. The effects are further dependent on the nature of post-operative treatment and experience.

UNDERGRADUATE PSYCHIATRIC EDUCATION AS REFLECTED IN FINAL EXAMINATIONS

CHARLES WATKINS, M.D. AND EDWARD KNIGHT, M.D.

This survey came about as a direct result of discussions by participants at the meeting of the Association of Southern Psychiatry Professors in December, 1956. These discussions clearly indicated that a high proportion of the participants were concerned as to what general course, if any, psychiatric education was taking at this time. The reason for this concern was the fear that their own programs might in some way be failing to utilize techniques or to include material of generally recognized value. Methods of evaluating results of teaching were also of concern.

As this anxiety was also held in our own department, we began to study possible methods of obtaining information about psychiatric education in general.

It became clear that if such a study was to be made, certain definite decisions as to limits must be decided upon. The first decision was that any study undertaken at this point should be a fact-finding one: no attempt to evaluate as to the suitability of content should be made. Our next decision concerned whether to attempt a direct or an inferential study of the curriculum of various schools.

The direct method of study involving visits to various medical schools offers very definite advantages. This type of study would give the investigator an opportunity to observe the actual teaching program being carried out, to discuss the program with both the non-participating and participating faculty, as well as with students and possibly with recent graduates. It is generally recognized that members of the department frequently do not have the same impression as to what they are teaching as do members of other departments and students. This method would involve considerable expenditure of time and money.

Unless it were conducted by a relatively large group of workers the time involved in the survey would allow for considerable modification in the teaching program between the time the first school was visited and the last. We felt that this method was impractical at this time and chose the indirect or inferential method of studying the teaching program.

A relatively simple type of survey could have been conducted by studying the outlines of the courses which are contained in the official school catalogues. Included in the usual catalogue are not only the hours allocated to the department, but a breakdown of hours by year and by title of course, and in most cases, comments as to the content of the course. There are exceptions to this, however, in that some schools do not list in the catalogue the number of hours various courses are taught. A disadvantage to this method is that the actual teaching schedule is frequently at variance to the time and title as outlined in the catalogue.

A third method of surveying content would be by the use of mimeographed material that is given to students. This would include lectures, bibliographies, and various other teaching aids. We felt that this would be a considerably more precise measure of the course than catalogue information, but that it would have a number of inherent disadvantages, one being that the material would in many instances be incomplete. It is frequently difficult to collect all of the material that is passed out to students during their teaching year after the courses have been organized or completed.

We finally decided upon written examinations as our subject of study. A study of this type is clearly only a tentative step toward a comprehensive survey of psychiatric education and we are offering this report in that light.

Questions asked on final examinations are, to some extent at least, a reflection of the general content of the courses they are designed to evaluate. There are certain serious

¹ Read at the 114th annual meeting of The American Psychiatric Association, San Francisco, Calif., May 12-16, 1958.

² Department of Psychiatry and Neurology, Louisiana State University, School of Medicine, New Orleans, La.

defects in the use of examination questions, however. Some schools do not give written examinations. Frequently the course grade is determined primarily by the clinical work, and examinations are given only to comply with university regulations. In such instances, the examinations tend to be brief and reflect little the nature of the course. Finally, there appears to be some reluctance on the part of psychiatrists to give comprehensive written examinations. In addition to the information obtained about content we felt that we might be able to arrive at some tentative conclusions about the attitudes of psychiatric educators toward examinations.

In spite of these disadvantages, certain advantages become evident. One is the fact that if the request for examination questions could reach the department at about the time of examination there should be a high probability of a response. Of the schools that did respond, it would be possible to check the examination questions against the curriculum as listed in the catalogue to determine whether or not the response appeared to be complete for the entire teaching program. Examination questions give us definite objective data that we could assess and readily quantify.

To collect the data we used as reference the directory of the Association of American Medical Colleges. All departments of psychiatry listed in it with the exception of the graduate departments were contacted. Letters were written to the department chairmen outlining our project and requesting that they send us copies of examinations given to their medical students during the year 1957. The letter was mailed late in May so that it would reach the schools at about the time of final examination.

In this study we are using information obtained from the 4-year medical schools in the United States and in Puerto Rico. It was felt that the inclusion of the Canadian schools might shift our results because of the difference in curriculum planning in Canada. Material from the 2 year schools will be reported later.

Number of U. S. Schools Contacted	78
Total Number of Responses	63
Responses from Two Year Schools	2
Responses Which Did Not Include Complete Sets of Questions	6
Total Number of Schools Included in Survey	55

The geographic distribution of schools used in survey is as follows: Eastern 17, Southern 16, Mid Western 16, Far Western 6.

In a previous report submitted to the Association of Southern Psychiatry Professors in January, 1958, we reported on the formal structure of the final examination in psychiatry. That report dealt with the use of objective and subjective questions, the use of the case report in the final examination and with the integration of the various disciplines in the examination, as well as with other aspects of formal structure.

Note was made upon the increase, or lack of increase of complexity of the examination during the 4 years.

Courses and examinations were given as follows:

	4 Years	3 Years	2 Years	1 Year	None
Courses taught	49	5	1		
Written examinations given	7	25	14	6	3

Of the total of 137 sets of examinations the distribution and the number of questions by year was as follows:

	1st Year	2nd Year	3rd Year	4th Year
Examination Questions	41	46	36	14
	1212	753	809	335

From these figures it is apparent that examinations are given most frequently in the first 2 years. The reliance upon the examination is much less during the clinical years when the student has a greater amount of personal contact with the teaching staff.

It is also obvious from these figures that any numerical breakdown of type questions has only relative value in the light of the total time allocated to the course. The short 18-32 hour lecture course in the first year was more likely to end with a final examination than was the much longer course offered in the third and fourth year.

The examinations of the individual schools were studied by year rather than as a whole because of the realization that the difference in hours and examination frequency necessitated this.

In our analysis of the questions, we used a somewhat arbitrary and unrealistically distinct breakdown in various categories of

subject matter. The questions were placed in the following categories: basic science, clinical, interdisciplinary.

Basic Science Questions were those considered to be related primarily to the area of normal development and function of the organism, even under stress. Questions were not considered to be in this category if they were clearly associated with clinical syndromes or symptoms. For example, a question related to the vicissitudes of the child during the anal period was considered to be basic science, while a discussion of the relationship of neurotic symptomatology to experiences undergone during the anal period was considered to be clinical.

Clinical Questions were those considered to be related to clearly stated medical problems, either as to understanding, description or management.

Interdisciplinary Questions were those which clearly recognized the role of the related disciplines, medical or otherwise in the care of the emotionally ill.

The groups were further subdivided in the following manner:

Basic Science

- a. Psychodynamic
- b. Other psychological theory
- c. Cultural
- d. Neurophysiological

Clinical

- a. Psychodynamic psychopathology
- b. Descriptive diagnosis
- c. Practical management

In addition, the clinical questions were evaluated as to whether they appeared to be related to psychiatry as a speciality or to the practice of medicine with a recognition and management of emotional problems by the nonpsychiatrist.

We quantified the material in the following manner. Examinations which seemed strongly oriented toward a particular emphasis were marked 2+. Sets with moderate or minimal emphasis were 1+. Those where we felt little or no emphasis were left blank.

The breakdown of the major points of emphasis using this rating scale and the consensus of two raters is shown in the table at the top of the next column.

It is clear that even in the first 2 years there is a strong emphasis upon the clinical aspects of behavior and some emphasis

Basic Science	1st	2nd	3rd & 4th
	Year	Year	Years
Psychodynamic	72	27	
Psychological theory (other)	13	8	
Cultural	16	11	
Neurophysiological	21	14	
Clinical			
Psychodynamic psychopathology	48	37	48
Descriptive diagnosis	40	51	46
Practical management	15	17	36

upon clinical management. It is worthy of note that the frequency with which the examinations were worded in psychoanalytic terminology decreased from 39 in the first 2 years to 15 in the clinical years. The total number of questions involving interviewing techniques and processes was 11 for the entire 4 years, most of which were in the second and third year.

General medical and nonspecialist clinical management totaled 50 in the first 2 years, whereas there were 40 points of emphasis in the third and fourth year. This must be evaluated in the light of the fact that there were fewer examinations given in the clinical years than the preclinical.

Relatively little emphasis was placed upon the care of the hospitalized psychotic, although most schools clearly indicated that the student was acquainted in general with this type patient.

There was little evidence of integrated team orientation throughout the examinations. Clinical psychological questions were frequently clearly separated from the psychiatric questions. The recognition of the role of the social worker and the psychiatric nurse was notably ignored in most instances.

It is interesting to note the relatively small number of examinations that give direct evidence of an expected personal growth change in the student as part of the study of human behavior. There was practically nothing involving group dynamics or group theory and very little pertaining to the psychological aspects of hospital administration.

The emphasis as far as age distribution is concerned is primarily on the adult, with a relatively high emphasis on children and adolescents, and a relatively slight emphasis on geriatric problems.

In going over the examinations we found that there appeared to be no notable em-

phasis in any one geographic area. In general the range of subject matter appeared to be fairly uniform throughout the country. In a small proportion of the examinations there was clear evidence of local orientation. These were worded in such a way that an outsider was unable to answer because of lack of familiarity with the semantics involved.

SUMMARY AND CONCLUSIONS

Only general suppositions can emerge from a survey of this sort with regard to content of the examinations. These are: There is a definite trend in the direction of teaching human behavior as a basic science. It seems to be implemented by the use of clinical material rather than basic psychological, cultural and neurophysiological data. Human behavior as a basic science is often approached by simply teaching the standardized conventional psychoanalytic theory of personality development, without adequately relating this approach to cultural and biological factors.

There is some hint of a peculiar dilemma facing psychiatric educators. Clinical psychoanalytic material was used to outline basic science phenomena. In clinical handling of patients these same principles could not be directly applied with ease, thus the handling of patients was by the usual pragmatic psychiatric methods. It is probable that this occurs because intensive psychotherapy is not usually possible during medical training. Therefore basic psychoanalytic science was not really integrated with clinical practice even though clinical analytic material was used in first two years.

DISCUSSION

Kenneth E. Appel, M.D. (Philadelphia, Pa.)—There are many reasons, for the dissatisfactions of teachers of psychiatry with their instruction and its absorption and comprehension. The G.A.P. report on psychiatric education forms an excellent orientation as does the book from the Cornell Conference, edited by Whitehorn.

Drs. Watkins and Knight's paper repre-

sents another method of evaluating undergraduate psychiatric education: through a study of final examinations. General trends appear in the study of 55 medical schools. Courses are taught in many schools in all 4 years. This is progress.

Examinations are given mostly in the first 2 years. The lessened frequency of examinations in the last 2 years poses certain questions. What are the reasons for this? Examinations are held in the other branches of clinical medicine. Is it felt there is not enough solid substance on which to examine? Is the staff not large enough adequately to deal with examinations in the latter years? Is there so much of a mixture of clinical material in the first years when basic science is to be taught that the question basket is drained dry?

It would seem to us that the study points to the importance of revamping teaching in the first 2 years. Human behavior can be taught as basic science, bringing in experimental literature and experimental demonstrations, whether from physiology, chemistry, psychology, sociology, or cultural anthropology. There is enough experimental and basic science literature at hand which correlates well with the other basic science courses in the technical school curriculum. It seems to us that bringing the students into vital contact with the research work going on in basic psychiatry would not only vitalize psychiatry but awaken responses in medical students to the fascinating challenges our science presents today, and thus develop recruits.

Many disquieting observations were made in the paper—one of them was the evidence of so little attention being paid to interviewing techniques and processes. This is important not only for the psychiatrist but for all practitioners of medicine in order to evaluate emotional and stress factors which are so common in the practice of medicine today.

Calling attention to defects will call to mind remedies and further discussions of professors of psychiatry, and let us hope they will not be limited to the Southern professors.

EMOTIONAL CONTENT OF SUICIDE NOTES¹

JACOB TUCKMAN, Ph.D.,² ROBERT J. KLEINER, Ph.D.,³
AND MARTHA LAVELL, M.S.S.²

Suicide, a subject for study, conjecture, and research throughout the ages, has been explained from many different viewpoints. Menninger utilizes the concept of self-directed aggression and amplifies it into a hypothesis which explains suicide as mainly the result of intrapsychic factors. He believes that suicide involves 3 motivational components, the wish to kill, the wish to be killed, and the wish to die, "deriving from primary impulses of destruction"(1). Fenichel explains suicide as a function of hostility directed against the self because "of a punishing superego that prevents expression of hostility"(2). Other writers subscribing to the relation between hostility and suicide give slightly different explanations of the source, direction, and intensity of hostility.

In classifying theories of suicide according to the various emphases given to the underlying motives of the suicidal act, Jackson mentions not only self-directed aggression but also (a) rebirth and restitution and (b) despair, loss of self-esteem, and the real or imagined loss of the love object(3).

Since hostility is an integral part of many theories, the purpose of this study is to test the hypothesis that suicide is a function of hostility. The relationship between affect and method of suicide as well as the social characteristics of the suicide will also be analyzed. The approach is one employed by Schneidman and Farberow(4), who analyzed the content of the suicide note, the last recorded verbal expression of the suicide. The significance of the note is based on the premise that its content represents the thoughts and affect of the suicide at the time of note writing and death. In effect the note is a projective product of the suicide's mind: the situation is totally

unstructured since no request has been made of the individual to produce a note and there are no norms to guide him about its content.

PROCEDURE AND RESULTS

In connection with an epidemiological study of 742 deaths classified as suicide by the Office of the Medical Examiner in Philadelphia over the period from 1951-1955(5), it was found that notes had been left by 24% of the group. A comparison of those who left notes with those who did not showed no significant difference between the two groups with respect to age, race, sex, employment, marital status, physical condition, mental condition, history of mental illness, place of suicide, reported causes or unusual circumstances preceding the suicide, medical care and supervision, and history of previous attempts or threats. However, there was a significant difference between the two groups in the method of suicide. Eighteen percent of those who left notes, compared with 8% of those who did not, used poison. Twenty-nine percent of those with notes, compared with 19% of those without notes, used firearms. Forty percent of those who did not leave notes, compared with 31% of those who did, hanged themselves. These findings about the lack of difference between those who left notes and those who did not are similar to those in the study by Schneidman and Farberow(6) which reported, however, a lower percentage of note writers (15%) than in this study.

The records in the Medical Examiner's Office showed that, of 178 individuals who left notes, it was possible to locate notes left by 165, the loss being due to administrative difficulties. Of this number, 35% were women; 7% were nonwhite. The group ranged in age from 16 to 83 years, with a median age of 54.5.

The notes varied in length from a few words to several pages. Some were scribbled in pencil on a scrap of paper; others were written on hotel or personal

¹ Read at the 124th annual meeting of The American Psychiatric Association, San Francisco, Calif., May 12-16, 1958.

² Division of Mental Health, Department of Public Health, Philadelphia, Pa.

³ Eastern Pennsylvania Psychiatric Institute, Philadelphia, Pa.

stationery; and one had been found on a dictaphone cylinder. Some notes bore definite salutations to relatives, friends, or police; others were not addressed to any specific person. Most notes bore a signature. Almost all had been left near the scene of the suicide or in a few cases on the person; others had been mailed to relatives and friends. With few exceptions, the notes were legible and coherent.

Thirty percent of the notes gave no clue about the reason for suicide. Nineteen percent gave physical illness as the reason; 11% referred to some aspect of mental disturbance; 11% mentioned marital difficulty or family discord; 11% gave vague reasons indicating that life was intolerable, e.g., "couldn't stand it any longer," "no way out," "hell on earth," "sick of everything." Four percent made reference to financial difficulty; 2% mentioned death of relatives; and 4% gave various combinations of poor physical and mental health, financial difficulty, and death of relatives. Eight percent gave reasons not readily classifiable.

Seventy percent of the group left only one note, 19% left 2, 6% left 3, and 6% left 4 to 6 notes, making a total of 247 notes. However, for the purposes of this study, all notes written by any one person were treated as one. The reasons were: first, in many cases, the distinction between singular and multiple notes was only apparent since a single note might carry messages to more than one person; second, it seemed more meaningful psychologically to consider the notes left by each person as a whole rather than separately. Thus, the number of notes referred to hereafter will be 165 instead of 247.

A preliminary content analysis of 27 notes selected at random suggested the following categories into which the notes could be classified according to affect, with hostility at one end of the scale and positive feeling at the other. Examples of notes in each category are given, with salutations and signatures omitted.

1. *Hostility Directed Outward.*

I hate you and all of your family and I hope you never have a piece of mind. I hope I haunt this house as long as you live here and I wish you all the bad luck in the world.

2. *Hostility Directed Inward.*

I know at last what I have to do, I pray to God to forgive me for all the many sins I have committed and for all the many people I have wronged, I no longer have the strength to go on, what I am about to do might seem wrong to a lot of people, but I don't think so, I have given it plenty of sober consideration.

3. *Neutral Affect.*

Everything I own goes to Miss ----- in case of my death.

4. *Positive Affect.*

Please forgive me and please forget me, I'll always love you. All I have was yours. No one ever did more for me than you, oh please pray for me please.

5. *Combination of Outward-Directed Hostility and Positive Affect.*

I am sorry I have to take this way out. But you can see there's no other way. She would just give me and the kids a hard time for the rest of our lives, also the club deal is away out of my hands contact S----- about the Girls and the M-----s about B-----. All the money I have in the world is here. May God Bless you and your family and may he look after mine.

May she rot in hell with me.

6. *Combination of Inward-Directed Hostility and Positive Affect.*

I am at the end of a rotten, stinking low life—What I have done in the last five years of my miserable life is even to much for me—I blame no one but myself—for if I was just a half a man with just a spark of decency in me—all this wouldn't have happened to me—I admit that I was pushed into it or should I say taken by the hand like a child introduced to a new toy—from then on I was on my own I lied and cheated and stold and borrowed from a cent on up—I did not draw the line on anything or anybody—

My Dear Sister I love you and B----- more than life itself—I have brought shame and heartaches for you both—Doing what I am about to do is the only decent thing that I can do with this miserable life—You see Sis *you* alone was the only one who understood what had happened to me—When I came back to being a free man once again I was determined and full of hope that this time I was going to make it—to put down on paper the obstacles and hazards that I had to over come would take me a week—small things like being shook down for what I happened to have in my pocket—pulled out of the movies and being embarrassed by rolling up sleeves—you see I

needed help in a lot of ways—The main thing was a job—I believe that if I had a fairly good job I would have made it—That was the biggest assist I needed but it never happened. J—— —you are a swell guy—an ace—to you I couldn't explain and make you understand why I did what I did.

Whats the use or to what purpose am I living—I pray to God to let me take my life.

The notes were classified independently by 4 raters⁴ according to the categories outlined above. In 48% of the cases there was complete agreement among the 4 raters; in another 30% of the cases there was agreement among 3. Using the paired-comparison method, the amount of agreement between any two raters varied from 70% to 84%. The average percentage of agreement was 77%. It is noteworthy that the amount of agreement was so high among raters from 3 different disciplines.

The classifications of the notes showed little hostility in pure form. Using the average of the 4 raters, outward-directed hostility was evident in only 5% of the notes and inward-directed hostility in 1%. More frequently, hostility appeared in combination with positive affect. Nine percent of the notes showed a combination of outward-directed hostility and positive affect; 7% showed inward-directed hostility and positive affect; and 2% showed a combination of the three. Considering all notes in which hostility was evident, in its pure form or in combination with positive affect, the data indicate that hostility is characteristic of 24% of the notes. By contrast, 51% of the notes were classified as expressing positive affect without hostility and 25% as neutral affect. The variation among the 4 raters was less for hostility (range between 22% and 28%) than for positive affect (39%-59%) and for neutral affect (18%-32%).

For purposes of relating affect to the personal and social characteristics of note writers as obtained from the medical examiner's records, it was necessary to arrive at one rating for each note. Accordingly, the raters jointly reviewed any notes on which agreement was less than 75% in order to reach a consensus. Each note was

then placed in one of the 3 categories: positive, neutral, or a combination.

There were significant age differences with respect to affect (Table 1). For those aged less than 45 years, 28% of the notes were hostile, 63% positive, and 9% neutral; but for those aged 45 and over, 16% were hostile, 49% positive, and 35% neutral. Thus both extremes of affect decreased with age, but hostility showed more decline.

TABLE 1

Affect	AFFECT IN NOTE AND AGE OF SUICIDE	
	Under 45 years n=54	45 years and over n=111
	%	%
Hostile	28	16
Positive	63	49
Neutral	9	35
	$\chi^2=20.11$	$df=2$ $P<.001$

Affect also differed significantly according to marital status (Table 2). In general, there was little difference among single, married, and widowed, except that married individuals showed somewhat greater positive affect. As might be expected, hostility was most evident in the separated and divorced individuals. For this group the notes showed hostility in 43% of the cases, compared with 12% to 16% in the single, married, and widowed.

TABLE 2

Affect	AFFECT IN NOTE AND MARITAL STATUS OF SUICIDE			
	Single n=33	Married n=71	Widowed n=31	Separated or divorced n=30
	%	%	%	%
Hostile	12	15	16	43
Positive	52	63	52	33
Neutral	36	21	32	23
	$\chi^2=5.53$	$df=6$	$P=.02$	

No relationship was found between affect and sex, and between affect and method of suicide. For some factors such as physical health, mental health, medical supervision, and history of mental illness, where information was lacking in a large number of cases, and for other factors such as race, living arrangements, and motivational content of the note where the data were too fragile, no statistical tests were made.

⁴The 4 raters included a psychiatrist in addition to the 3 authors.

The hypothesis that suicide stems solely from negative affect is supported by the content of the notes. Although there is a mixture of affect from positive feelings being noted in half the notes, the most neutral feelings noted in 21% of the notes, found also in 26%. The assumption is that the neutral content of the note represents the true emotions of the individual at the time of suicide. The notes with few exceptions seem to be very coherent, clear, and to the point, and not covering up or fabricating, but rather show a sort of clarity and a tendency to sum up life's experiences.

The finding of a range of affect in the notes seems to suggest a multiplicity of factors in suicide. There is an interplay of emotional conflicts and reality frustrations but the pattern of the interplay varies with age. In the younger suicide, interpersonal and intrapsychic conflict may create or intensify environmental stresses, whereas in the older suicide such conflict stems more from reality problems such as old age, reduced income, or poor physical health, i.e., factors beyond his control.

In this study the writers were impressed with the possibility that in a number of cases the suicide could have resulted from a conscious, rational decision reached by weighing the pros and cons of continuing to live, although to a lesser extent unconscious factors may have been operating. Particularly in the older age groups there appears to be loss of morale in the light of physical illness or economic plight, and a desire to achieve a tensionless worry-free state. The wish for relief from dissatisfying life experiences becomes so strong that thoughts are not of self-destruction but of relief from extreme discomfort. Jackson also makes the point that "suicide is a symptomatic act, not a discrete entity." He further postulates a continuum: "at one extreme would be the 'irrational' suicide who kills himself entirely because of inner emotional make-up, while at the other extreme would be a 'rational' suicide who destroys himself because of external conditions; in between would be the 'neurotic suicide' under some daily emotional strain and the lonely aged person. Thus suicide can be viewed as a combination of

the individual's inner emotional make-up and external stress or extreme social pressures—a concatenation of 'psychic forces' and 'environmental factors' (3).

Organized society is opposed to suicide, as it is the antithesis of racial preservation and also because it allows a loophole by which individuals can escape from the authority of the state and the church. Suicide has been regarded as a sin and a crime in many cultures, some of which have punished it by such means as mutilating the corpse. It is small wonder, then, that suicide is often considered an "irrational" act derived largely from unconscious (hostile) impulses.

The finding of positive sentiments in half the notes suggests that suicidal individuals can be worked with toward a resolution of their problems, with their positive feelings providing an important motivational force. This has implications for preventive programs. There is evidence in the literature that a substantial number of those committing suicide had made previous suicidal attempts or threats(7) or had shown other evidence suggesting a suicidal tendency. Consequently, when these individuals are identified and referred for appropriate psychiatric care, the recognition of the presence of positive affect may indicate a more favorable prognosis than hitherto realized.

SUMMARY AND CONCLUSIONS

1. An analysis was made of the emotional content of notes left by 165 suicides in Philadelphia over a 5-year period. Over half the notes showed such positive affect as gratitude, affection, and concern for the welfare of others, while only 24% expressed hostile or negative feelings directed toward themselves or the outside world, and 25% were completely neutral in affect.

2. Persons aged 45 and over showed less affect than those under 45, with a concomitant increase in neutral affect.

3. Persons who were separated or divorced showed more hostility than those single, married, or widowed.

4. It is believed that these findings have certain implications for further understanding of suicide and ultimate steps toward prevention. The recognition that positive

neutral feelings are present in the majority of cases should lead to a more promising outlook in the care and treatment of potential suicides if they can be identified.

6. Shuchman, Elmer S., and Elizabeth Norton L. Gillet: *On Suicide*, pp. 100-101. *Psychiatry*, 7:1, p. 1.

Fifteen percent of the group had side reactions, which were readily relieved by reduction of dosage or temporary withdrawal; 81% showed improvement; slight, 27.2%; considerable, 21.2%; great improvement, 33.1%.

In 60 patients chosen at random the blood pressure drop was 12 mm. systolic and 9 mm. diastolic. Tachyphylaxis to this slightly hypotensive action of perphenazine develops more rapidly than with Thorazine.

Patients who went home were advised to continue their maintenance dose of Trilafon indefinitely and were given the opportunity to return for a check-up every 6 weeks. Few made use of this privilege but many who did have been taking Trilafon for 3 years with no deleterious results and their psychoses continued to be in remis-

sion, while blood and liver function studies remained normal.

Trilafon repetabs are the preferred form of oral medication among both hospitalized and out patients because they provide a sustained plateau of action, save time for nurses, attendants and patients and decrease the possibility of omitting a dose in extra-mural care.

Trilafon, in properly individualized dosage, administered for a sufficient length of time, has a most satisfactory therapeutic index because of its high potency and relatively few and benign side reactions. It is more active parenterally than orally. Trilafon is effective in a high percentage of neuropsychiatric patients, the behavioral improvement was 81.5% betterment in this study.

A STUDY OF THE VALUE OF THE FUNKENSTEIN TEST AS AN INDICATOR OF THE EFFECTIVENESS OF ATARACTIC DRUGS

MANFRED BRAUN, M.D., AND SEYMOUR RETTEK, M.D.¹

Thirty patients were tested to observe the correlation between their physiological response to the Funkenstein test and their clinical response to the ataractic drugs, such as reserpine, a derivative of *Rauwolfia* and chlorpromazine, a derivative of Phenothiazine. The patients, all males, aged from 20 to 50 years, were in good physical health and diagnosed either as schizophrenics or personality disorders in whom anxiety was a major symptom.

The Funkenstein test was given in the usual way. 1. Mecholyl 10 mgs. was given intravenously under basal conditions one day, and epinephrine 0.05 mgs. were given intravenously the following day. Each time the effect on the blood pressure and the time necessary for return to normal were measured. This was followed by the administration of chlorpromazine 50 mgs. t.i.d. for 2 weeks, in turn followed by reserpine 0.5 mgs. t.i.d. for 2 weeks. The double blind method (2) was used for clinical evaluation which was done both

before and after each period of drug administration.

There were no untoward effects resulting from the Funkenstein test. According to the blood pressure response as described by Funkenstein (3), 5 patients were mecholyl sensitive and 6 were epinephrine sensitive. No patient was found to be sensitive to mecholyl and epinephrine. Three patients showed clinical anxiety upon the administration of mecholyl and 4 showed anxiety with the administration of epinephrine, but in no case were they the same patients who were either mecholyl or epinephrine sensitive according to the blood pressure response.

RESULTS

Seven patients showed significant clinical improvement with chlorpromazine, one patient showed significant clinical improvement with reserpine, and one became depressed with the administration of reserpine. The patients who showed a response to the drugs were from the group which showed neither mecholyl nor epinephrine sensitivity.

¹ VA Hospital, Bronx, New York.

Comparing the results of the response to the Funkenstein test with the clinical response to treatment with chlorpromazine and reserpine, we found that the test offers no prognostic indicator as to the clinical effectiveness of either of the two drugs tested. An interesting result is that those patients who showed no response to the Funkenstein test seemed to have the great-

est improvement with chlorpromazine. Seven of the 12 patients showed a considerable improvement with the drug (See Table 1).

TREATMENT OF AFFECTIVE DEPRESSION WITH TRANS-DL-PHENYLCYCLOPROPYLAMINE HYDROCHLORIDE :¹ A PRELIMINARY REPORT

MAGNUS C. PETERSEN, M.D.² AND JOHN W. McBRAYER, M.D.³

Between December 1, 1958, and March 3, 1959, a total of 52 patients were treated with trans-dl-phenylcyclopropylamine hydrochloride at the Rochester (Minnesota) State Hospital. Patients' ages ranged from 24 to 85 years (average 54.7 years). All were women suffering from affective depression of various types. Thirty-eight were admitted during the specified period, in order, 13 were selected patients who had not responded to other forms of treatment over prolonged periods, and one patient was treated entirely on an outpatient basis.

The compound was given orally, commencing with 10 mg. twice a day. In most cases this dose was sufficient. In a few instances it was increased to 10 mg. 3 or 4

times daily. One patient received 20 mg. twice a day.

At the end of the period 21 patients had recovered, 15 were much improved, 6 were slightly improved while 7 remained unimproved. In 3 cases the treatment was terminated before sufficient time for evaluation had elapsed. Seventeen patients had been dismissed from the hospital and 11 were ready for dismissal. Since a number of the other patients under treatment were improving, the result undoubtedly will be better as time passes.

In 8 cases in which the danger of suicide was great or the improvement was not great after a few days, electrotonic treatment was administered in addition to the medication. In most instances only a few electrotonic treatments were necessary. No difficulty was encountered with this procedure except for prolonged apnea in one patient after the first treatment.

A decrease in blood pressure was noted

¹ This compound was supplied gratis for purposes of clinical study, under the designation of "SKF 385," by the Smith Kline & French Laboratories, Philadelphia, Pa.

² Rochester State Hosp., Rochester, Minn.

³ The Mayo Foundation, Rochester, Minn.

in all the patients treated. Orthostatic hypotension developed in one patient. On the fourth day of medication, with a dose of 10 mg. twice a day, this patient complained of dizziness. The blood pressure was found to be 210 systolic and 90 diastolic, in millimeters of mercury, when she was lying down and 110 systolic and 72 diastolic, when standing. Use of the medication was discontinued immediately, and the hypotension disappeared within 4 days.

Insomnia was a universal complaint. A mild soporific agent, such as ethchlorvynal (placidyl) or diphenhydramine hydrochloride (benadryl), given at bedtime, sufficed to establish regular sleeping habits within a short time.

Some preliminary electroencephalographic observations were made in 5 patients by Dr. G. E. Chatrian. In 4 patients no major changes were noted between recordings before the treatment was commenced and tracings after 7 days of medication consisting of 10 mg. of the drug twice a day. When these patients, in whom orthostatic hypotension did not develop, changed from the lying-down to the erect position the recording often was disturbed by muscular, ocular and mechanical artifacts. When the record-

ing was readable no noticeable slowing was observed. Similarly, no slowing of the electroencephalographic rhythms was observed in one patient in whom orthostatic hypotension developed. In this patient no recordings were taken before the hypotension developed.

The mental response to treatment with the drug usually was very rapid. In many instances both depression and agitation were greatly diminished within 24 hours, and had disappeared altogether within a few days. A high percentage of the patients could well have been treated entirely on an outpatient basis, had we been conversant with the effects of the medication. By the same token, many others could have been dismissed from the hospital much earlier than they were.

So far, all the patients who have been dismissed from the hospital continue to take the compound. In some cases the dose has been reduced. All are returning to the hospital regularly for follow-up studies. How long use of the medication should be continued or how soon it may safely be discontinued will be subjected to further study. To the present there has been no relapse.

THE USE OF TRIFLUPROMAZINE WITH IPRONIAZID FOR THE TREATMENT OF CHRONIC SCHIZOPHRENIC PATIENTS

ROGER F. REINHARDT, M.D., SAMUEL B. SCHIFF, M.D.
AND E. ROBERT SINNETT, Ph.D.¹

This study was undertaken to determine whether the combination of triflupromazine and iproniazid² would have more beneficial effects upon a group of chronically ill, withdrawn, apathetic, and regressed schizophrenic patients than triflupromazine alone. It was hypothesized that iproniazid, a psychic energizer, might aid in increasing interest, energy level, and participation in activities(1, 2), while triflupromazine, a tranquilizer, might decrease the irritation, tension, and exacerbation of disturbing

thoughts and feelings which have been found to accompany administration of the former(3, 4).

Twenty schizophrenic women were paired as to age, depth of regression, chronicity of illness, and apathy. Using the double-blind method over a 3 month period, triflupromazine and iproniazid were administered to half the patients as the experimental group, while triflupromazine plus a placebo were given to the control group. The patients received no medications for 2 weeks prior to the start of the project; they were rated on behavioral scales before being given the drugs and then at 2 week intervals. The initial dosage

¹ VA Hospital, Topeka, Kan.

² Triflupromazine was supplied as Vesprin by E. R. Squibb & Son, iproniazid as Marsilid by Roche Laboratories.

was 50 mgs. t.i.d. for each drug, and after 2 weeks the levels were adjusted as deemed necessary for the individual patients. It was necessary to discontinue the iproniazid in only one instance because of ataxia and hypotension. Side effects observed were those previously described by other authors. The ratings were made by the ward physician who evaluated accessibility of the patients, two nursing assistants who considered manageability (5 scales) and sociability (2 scales), and a corrective therapist who rated the patients on a dimension of involvement in activities.

There were no statistically reliable differences between the two groups prior to medication. Afterwards there was no significant improvement for the experimental group in any of the 9 dimensions. For the control group, however, significant improvement occurred on 3 of 9 scales: Dressing, Personal Hygiene, and Participation in Activity Program. A cross-comparison of the amount of improvement in the experimental group *vs.* the amount of improvement in the control group showed statistically reliable more improvement on one scale, Participation in Activity Program, and a trend toward significantly more improvement in Dressing.

The findings refuted the hypothesis that the combination was superior to trifluor-

mazine alone, as patients receiving both drugs failed to improve, while those receiving the single drug made a significantly better hospital adjustment. Favorable changes in the group receiving trifluorpromazine alone seemed to cluster more on manageability and activity participation as opposed to improvement in interpersonal relationships. The relative superiority of trifluorpromazine would appear to be limited to improvement within the hospital, there being no difference in discharge rates for the two groups one year later.

It would seem that in the treatment of chronic schizophrenics the combination used is not an effective one, and that trifluorpromazine cannot afford sufficient tranquilization, within the dosage range prescribed, to overcome the undesirable effects of the iproniazid.

CLINICAL AND STATISTICAL EVALUATION OF RESULTS WITH PLEGICIL AY-57062 IN CHRONIC MENTAL PATIENTS

E. J. TOLAN, M.D.,¹ J. OLARIU, M.D.,² J. M. REES, M.D.,³ AND H. A. PEPPEL, M.D.⁴

Acepromazine (Plegicil)⁵ is a relatively new phenothiazine derivative, closely related to chlorpromazine. Its basic properties are very similar to those of chlorpromazine though minor differences were noticed.

The early pharmacodynamic and clinical studies suggest that this drug has essentially the same indications, but it is about twice as active as chlorpromazine and the incidence of serious side effects is very low (2-9).

³ Staff Psychiatrist at Hawthornden State Hospital, Macedonia, Ohio.

⁴ Superintendent, Hawthornden State Hosp., Macedonia, Ohio.

Statistical work by M. H. Halbert, Case Institute of Technology, Cleveland, Ohio.

⁵ Plegicil was offered as a courtesy by Ayerst Laboratories, New York City.

SELECTION OF PATIENTS

A true random selection of cases from the entire hospital population was not attempted, instead we used each patient as his own control.

We segregated a group of patients who exhibited the following common traits:

1. Failure to respond to tranquilizing drugs,

EST and psychotherapy. 2. Poor prognosis due to long periods of hospitalization, regression, etc.

The series under study included 12 male and 36 female patients. Their ages ranged from 22 to 61 years. The number of years elapsed since their first admission to the hospital ranged from 1 to 29 years.

The diagnostic categories were primarily schizophrenic reactions, 44 cases. The rest of the group included 2 manic-depressives, manic type; 1 mental defective with psychosis; and 1 patient with chronic brain syndrome associated with alcoholism.

Dosage and Administration. The total length of acepromazine administration ranged from 1 week to 26 weeks. The total amount administered in one course ranged from 0.280 Gm. to 8.080 Gm., the highest daily dosage ranged from 40 mg. to 120 mg.

SIDE EFFECTS

No noticeable side effects were encountered, with the exception of 3 patients in whom the medication had to be discontinued. These 3 patients presented troublesome untoward reactions, manifested by extreme agitation, confusion, shakiness, marked weakness, and unsteadiness.

SUMMARY

Acepromazine was tried in 48 chronic mental patients, 12 male and 36 female. Their ages ranged from 22 to 61 years, and the time elapsed from their first admission in a mental hospital ranged from 1 to 29 years.

The majority of the patients were suffering from various types of schizophrenic reactions, and no significant number of other diagnostic categories was included.

Acepromazine was administered orally for an average of 16 weeks. The highest daily dosage reached 120 mg., with an average of 99.58 mg. The drug *did improve* symptoms and behavior in a significant manner.

Thirty-seven out of the 48 patients showed some improvement; 7 showed no change; 1 patient worsened. The other 3 patients worsened and developed toxic reactions; the medication was discontinued

and the patients were removed from the study.

There was a slight indication that younger patients and those admitted recently were helped more than older patients or those whose first admission was many years ago. There was no significant difference in the effect of acepromazine on various diagnostic categories. There was no relation between the total length of the medication and the degree of improvement. There was a *slight* but not significant indication that a slower increment in dosage results in greater improvement than a faster increment. Two main areas, Psychotic Symptoms and Behavioral Traits, improved more than Intellectual Resources, Character Traits and Interpersonal Relationships, and Socialization and Rehabilitation, but the improvement in Behavioral Traits is not significantly correlated with the improvement in the Psychotic Symptoms.

With the exception of 3 patients for whom the drug had to be discontinued because of toxic reaction characterized by extreme agitation, confusion and weakness, very few side effects have occurred and none was serious. No jaundice or allergic reactions were noted, and a very low incidence of Parkinsonism was encountered. No relation was found between the number or the type of the side effects, including Parkinsonism, and the degree of improvement.

Finally, it was noted that in this series of patients, acepromazine proved effective where other drugs or EST were not and that of the 7 patients who showed no improvement on acepromazine, none had improved on previous chemotherapy or EST.

CLINICAL RESULTS WITH PHENELZINE

JOHN C. SAUNDERS, M.D., RICHARD W. ROUKEMA, M.D.,
NATHAN S. KLINE, M.D., AND SAMUEL D'A. BAILEY, M.D.¹

Previous reports(1-4) have described the value of monoamine oxidase inhibitors in the treatment of depressed states. The majority of such successfully treated cases have been of the endogenous (essential, true, primary) type; other authors have noted fair to moderate results in treating depressed, withdrawn and catatonic schizophrenics. Still others have used the monoamine oxidase inhibitors in manic-depressive, depressive psychosis, with good results. Psychopharmacologic therapy is most effective for symptomatic indications not on generalized diagnostic entities.

We have employed phenelzine² in depressed patients regardless of diagnostic classification for the past year in an effort to determine the efficacy of the drug in the following conditions:

1. 24 adult, chronic, male schizophrenics characterized by depression and withdrawal.

2. 20 markedly depressed males, some of whom had catatonic-like features.

3. 5 acute, depressed, non-psychotic patients.

4. 12 non-hospitalized, ambulatory depressed patients from private practice.

The average daily dose was 15 mg. b.i.d. or t.i.d. The usual course of treatment was 6 months; the maximum, 9. Some ambulatory, non-hospitalized patients received phenelzine for less than 6 months. When maintenance therapy was required, one tablet daily was administered as indicated.

In Group 1 some improvement was noted in depressive symptoms, thus enabling 3 of the 24 patients to be discharged. The remaining patients, although revealing some improvement in apathy and autistic tendencies, showed no basic change in their schizophrenia *per se*.

In the second group of chronic schizophrenics, activity was increased in every patient: 4 of the patients actually demonstrated agitation, aggressiveness and hostility so that the dosage had to be reduced, and/or a tranquilizer administered.

None improved sufficiently to be discharged but it should be pointed out that phenelzine is not intended as a specific for schizophrenia.

All patients in the third group achieved recoveries from depression within 10-15 days.

The fourth group demonstrated very dramatic results with phenelzine. It should be noted that this drug may be more specifically indicated for use with ambulatory patients where there is some evidence that lower dosage and shorter duration of treatment will suffice.

Phenelzine has shown no evidence of severe side reactions after 16 months' clinical trial. Previous history of liver disease may be a contraindication for phenelzine therapy. However, our patients were subjected to a battery of clinical studies, including thymol turbidity, cephalin flocculation, alkaline phosphatase, A/G, and BUN without significant abnormalities. Occasionally an individual, usually non-hospitalized,

¹ Rockland State Hospital, Orangeburg, N. Y.

² Phenelzine has been supplied as Nardil through the courtesy of Warner-Chilcott Laboratories.

would show mild to moderate postural hypotension ; this was easily managed by bed rest or reduction of dosage. It is our opinion that phenelzine is an effective and useful drug in the treatment of various types of depression. Almost without exception, patients with endogenous (essential, true, primary) depressions responded favorably to phenelzine.

HISTORICAL NOTES

A NOTE ON PLINY EARLE AND EDGAR ALLAN POE

JEROME M. SCHNECK, M.D.¹

In 1957 two letters by Edgar Allan Poe were brought to the United States and attracted considerable attention. One of these letters had been addressed to H. S. Root. It was considered a rare item with the unusual attribute of possessing the full name of Poe in its signature. This letter made reference to Dr. Earle. In a letter to *The New York Times* I was able to identify the physician as Pliny Earle, one of the most distinguished American Psychiatrists and a founder of the American Psychiatric Association. Poe and Earle had corresponded briefly and Earle's book, *Marathon and Other Poems* was published in 1841. It was pointed out that as his career in psychiatry blossomed, he discontinued writing poetry. Poe's letter reads as follows:

New York
June 28-49.

Dear Sir ;

I regret to say that I am unable to answer your query. I have not seen a volume of Dr.

¹ Clinical Assoc. Prof. of Psychiatry, State University of New York College of Medicine, N. Y. C. Address : 26 West 9th Street, New York 11, N. Y.

Earle's very beautiful poetry for many years and I fancy the edition—(one only was published)—is out of print. The Doctor himself, when I last heard of him, was Superintendent of the Asylum for the Insane, at Bloomingdale, near this city.

H. S. Root Esq^{re}

Very respectfully
Yr. Obed^t S^t
Edgar Allan Poe.

In recent years there appears to have been an increase in interest in the history of American psychiatry. It is worth calling attention to this item now in a psychiatric publication should the Poe letter become less accessible later on when biographical data on Earle may be sought. Additional references to Poe's contact with Earle and to Earle's poetry are available in Pliny Earle's memoirs, edited by F. B. Sanborn.

ADMINISTRATIVE NOTES

EXPERIENCES IN THE CONVERSION OF A CLOSED TO AN OPEN PSYCHIATRIC WARD IN A GENERAL HOSPITAL

KISIK KIM, M.D.¹ AND MERRILL T. EATON, JR., M.D.²

On the basis of reports of successful open psychiatric wards(1, 2, 3, 4, 5, 7), it was decided to convert the psychiatric ward of the Kansas University Medical Center from a fully closed ward to an open ward. The plan was to devise a gradual method of change so as to minimize resistance or anxiety on the part of personnel and to disrupt other routines as little as possible; and to study the reactions of patients and personnel and to determine whether the change could take place without special facilities, additional personnel, or other modifications.

In planning this project for one year, allowing several months for preparation and gradual changes and a few months of complete open ward operation, it was decided to postpone any changes in admission policy or treatment methods other than those necessitated by the experiment.

The change was made on a 33-bed ward to which all types of psychiatric patients, both voluntary and on court order, were admitted. Most patients remained on the ward from 30 to 90 days. In the absence of hospital grounds suitable for informal recreation and because of the need for patients to be available for diagnostic studies, ward rounds, treatment, and teaching activities, it was not possible for them to go and come as freely as in some open hospitals(8). The patients would remain on the ward without locked doors or restraint, except when permitted to go elsewhere.

Devices which have aided some open hospitals include special organizations and group meetings, additional personnel, and early application of somatic therapies (for example, ECT in the first few hours after admission)(9, 10). It was hoped to defer

such steps, if possible, until it was determined whether the open ward could operate without them.

The advantages of open wards are largely theoretical. Whether they can be proven to shorten hospital stays or to increase rates of recovery cannot be determined without controlled studies of comparable wards. Likewise, an adequate measure of the relative incidence of complications would be beyond the scope of this project. The advantages are thought to include preservation of patients' self-esteem and improved cooperation through the elimination of authoritarianism(3). Improved attitudes of patients' relatives toward hospitalization and favorable changes in the attitude of personnel toward patients have been attributed to open wards.

Possible disadvantages include more patients leaving without permission, increased suicide risks, and acting out behavior. There is some question as to whether locked doors really reduce these risks.

In this experiment the conversion to an open ward was divided into 3 stages. In the first stage the principles underlying the open ward were discussed in meetings with personnel without direct reference to plans for the change and reprints of papers on the subject were circulated. In the second stage a committee was appointed, including a nurse, a staff physician, an occupational therapist, a recreational therapist, and a psychiatric aide. The *announced* purpose of the committee was to plan steps in opening the ward and discuss them with groups of employees. An *unannounced* purpose was to "sell" the idea to committee members and involve them personally in making the project a success. During this stage recreational and occupational therapy areas were unlocked for brief periods and the living room of the ward was unlocked during visiting hours. The third stage consisted of gradually extending the time that areas

¹ Research Associate, Nebraska Psychiatric Institute, Omaha, Nebr. Formerly Instructor in Psychiatry, University of Kansas Medical Center.

² Associate Professor of Psychiatry, University of Kansas Medical Center, Kansas City 12, Kan.

were left open and increasing the number of areas opened. Though the design of the ward would have permitted retention of a small locked area for a few disturbed patients, it was decided to open all portions since if any patient should be "locked up" other patients might fear this.

The attitude of personnel to the progressive changes followed a pattern of (a) initial vague acceptance or skepticism; (b) early hyperalertness and or hypersensitivity to minor incidents; (c) re-examination, inaction, and delay; and (d) ultimate acceptance or rejection. The attitude of the committee paralleled that of individuals. Representative of the period of inaction was a period of several weeks in which the committee had no reportable activity.

Each time a new area was unlocked or the time open increased, personnel were at first allowed to re-lock the areas when they deemed it necessary. This permission seemed to handle the early exaggerated fears of responsibility and made not locking the areas a matter of pride.

Psychiatric aides accepted the change more rapidly than nurses. Employees working in the afternoon seemed slower to accept unlocking than those in the morning. This was explained by a sense of security during the early part of the day when "more people are around," even though a majority of them are not attending patients.

Resistances and misunderstandings in the early phases of conversion included the repeated idea that unlocking of doors meant that patients could go out at any time and that this would complicate the work of personnel in locating patients for necessary activities. Pointing out that patients on general medical wards go and come only by arrangement partially dispelled this idea. The creation of a patient location board with magnetized name plates which could be moved to show the location and activity of each patient helped with this.

Another idea that recurred was that it would be necessary to station guards at the doors. This idea was difficult to eliminate. It returned in disguised form with a proposal for a sign-out desk just outside the ward. At times one would find an aide repeatedly leading a patient away from a

door. The idea of engaging patients, patients and groups in activities near the watching areas was difficult to eliminate.

The attitude of patients was generally favorable to the changes. New patients were more easily encouraged to enter voluntarily.

During the early stages one paranoid patient, who habitually sat near exits and attempted to slip out, noted during occupational therapy that hospital employees came and left without keys. She called the occupational therapist over and asked whether the therapist knew that the door was unlocked. After the situation was explained she abandoned her usual seat by the door and began to participate in occupational therapy.

There was no increase in the number of patients leaving the hospital without permission. With one exception, all patients who left returned voluntarily or were brought back by their families. The one who did not return could have been returned by her family had they wished. No accidents occurred as a result of patients departing without permission. No changes in treatment routines were necessary. Diagnostic studies were completed before treatment. There was no increase in the use of sedation or other somatic treatments. Psychotherapy remained the principle mode of treatment.

No changes in admission policy were necessary. The open ward was explained to those calling about admission of cases who might have had court charges pending or who had presented a run-away problem. This led to two cancellations of admission requests during the year. In one of these, an adolescent with a run-away problem, the possibility of special nurses was considered.

SUMMARY AND CONCLUSIONS

A method of gradual conversion from closed to open ward is described and the reaction of employees and patients is discussed. A closed ward in a general hospital can be opened without additional personnel and without modification of treatment methods or admission policies.

COMMENT

PHILADELPHIA MEETING HIGHLIGHTS

The 115th annual meeting of The American Psychiatric Association was held in Philadelphia, Pa., with headquarters at the Bellevue-Stratford Hotel, April 27 through May 1, 1959. Business meetings and scientific sessions were held in the Trade and Convention Center. This was the first annual meeting in Philadelphia since 1944, when the Centennial Meeting was held there, and the 12th meeting in the City of Brotherly Love. The first meeting of the Association was held in Philadelphia at the Jones Hotel on October 16, 1844.

The membership was pleased to visit the new psychiatric facilities in the city and especially the magnificent addition to The Institute of the Pennsylvania Hospital, an addition that is worthy of the traditions of its great superintendent and the Association's early president, Dr. T. S. Kirkbride.

Dr. Francis J. Gerty, President, called the Opening Exercises to order at 9:00 a.m. on April 27. The Invocation was presented by the Right Reverend William P. Roberts, D.D., former Bishop of Shanghai. His Honor, Richardson Dilworth, Mayor of Philadelphia, gave a welcoming address to the members. Following the introduction of the President-Elect, Dr. William Malamud, by the President, a number of information reports were read. Presenting his first report as Medical Director, Dr. Matthew Ross emphasized his intention to improve communication within the Association, to come to know the membership better through personal visits and letters, and to promote the welfare of the Association and the profession through the activities of the Central Office. Dr. Walter H. Obenauf, Speaker of the Assembly, noted the achievements and increasing responsibilities of the District Branches. Dr. Theodore L. Dehne, who served as Co-Chairman with Dr. Lauren H. Smith, reported briefly for the Committee on Arrangements. Program Committee Chairman Dr. John Donnelly pointed out special features of the meeting and noted that the program in-

cluded 174 scientific papers and 26 Round Tables. Due to the illness of Dr. C. H. Hardin Branch, the Secretary, Dr. Lawrence Kolb, elected Secretary, *pro tempore* by the Council, announced the official membership count as of March 31, 1959 as 10,420. The Treasurer, Dr. Robert H. Felix, reported a favorable financial condition for the Association. (His complete report will be included in the Annual Proceedings of the Association, to be published in a future issue of the Journal.) Dr. John I. Nurnberger, Chairman of the Hofheimer Prize Board, presented the Prize to Irving L. Janis, Ph.D., Associate Professor of Psychology at Yale University, for research described in his book *Psychological Stress: Psychoanalytic and Behavioral Studies of Surgical Patients*. Dr. Nurnberger commented upon the fact that the last three awards have been made to those with Doctorate degrees in Psychology. The eighth winner of the Isaac Ray Lectureship Award was Dr. Maxwell Jones, eminent British psychiatrist, for furthering understanding between law and psychiatry. As recipient, Dr. Jones will deliver a series of lectures on psychiatry and the law at George Washington University, in Washington, D. C., during the next academic year. The presentation was made *in absentia* by Dr. Frank J. Curran, Chairman of the Isaac Ray Board. Dr. Ross then announced the winners of the Mental Hospital Achievement Awards for the 1958 competition. Following the election of new members by the membership in accord with the recommendations of the Membership Committee and the Council, Dr. Gerty delivered his Presidential Address entitled "The Physician and Psychotherapy."

His address provided a most thoughtful discussion of psychotherapy as a basic treatment procedure in psychiatry and the needs for its wider instruction in the medical schools and amongst practitioners of medicine and psychiatry. Dr. Gerty's great judgment and wisdom were best shown in his consideration of the role of the psy-

chologist in relation to the practice of psychotherapy and the position that might best be held by psychiatrists in fostering the growth of psychotherapeutic practice.

Dr. Malamud, President-Elect, was respondent. The Opening Exercises were closed with a moment of silence in memory of members of the Association who had died since the last annual meeting, and a Memorial to Past-President Edward A. Strecker which was read by Past-President Kenneth Appel.

The second business session was called to order Tuesday afternoon at 2:00 p.m. Dr. John E. Davis, a member of the Board of Tellers, announced the results of the election of officers for 1959-60: Dr. Robert H. Felix, President-Elect; Dr. S. Spafford Ackerly, Vice-President; Dr. Franklin G. Ebaugh, Vice-President; Dr. C. H. Hardin Branch, Secretary; Dr. Addison M. Duval, Treasurer; incoming Councillors: Dr. Calvin Drayer, Dr. Paul Hoch and Dr. A. B. Stokes. Reports were presented by the three Coordinating Committee Chairman; Dr. Frank J. Curran for the Committees on Technical Aspects of Psychiatry, Dr. Wilfred Bloomberg for the Committees on Professional Standards, and Dr. Paul Lemkau for the Committees on Community Aspects of Psychiatry. Dr. Kolb then read a proposed amendment to the Constitution which will be presented to the membership for consideration on the next annual ballot. After a brief recess, the annual Convocation for newly elected Fellows began at 3:00 p.m. with Dr. Gerty presiding. Dr. Lauren H. Smith and Dr. Theodore L. Dehne served as Grand Marshals. An inspiring and scholarly Fellowship Lecture was presented by Dr. Karl A. Menninger, Life Fellow, on the neglected topic "Hope."

The next business session was held on Wednesday morning, April 29, in the Convention Hall Auditorium at 9:30. The Secretary's report to the membership was presented by the Secretary, *pro tempore*, in which he reviewed the major actions of the Council since the last annual meeting. The complete actions of the Council for this period will be published later in the Journal. The Secretary's report was approved by vote of the membership. Dr. Gerty awarded Certificates to the Officers,

Councillors and the Committee Chairmen who were retiring from office at this annual meeting.

On Wednesday evening the Annual Dinner was held in the Ballroom of the Bellevue-Stratford Hotel, followed by dancing.

At the final business session at 9:00 a.m. on Friday, May 1, the actions taken by the Council on April 30 were reported including the appointment of Dr. Paul E. Huston to fill the unexpired term as Councillor for Dr. Addison M. Duval, who had been elected Treasurer, and approval of the Rhode Island District Branch. These actions were approved by the membership on motion from the floor. Dr. William Malamud was then installed in the office of President for 1959-60. He announced the new officers for the Assembly of District Branches as Follows: Dr. Alfred Auerback, Speaker; Dr. John R. Saunders, Speaker-Elect; and Dr. Lester Shapiro, Recorder.

The total registration for the Meeting was 5,104, marking this as one of the largest on record; of this number, 2,540 were members. Approximately 70 science writers and reporters from the nation's leading newspapers and wire services covered the meeting for the public. The Association was honored by the attendance of many psychiatrists and guests from other countries.

The Association is greatly indebted to the able and outstanding leadership of its President, Dr. Francis Gerty, for the highly successful meeting, to his aides and the membership. In particular, great gratitude is due to the splendid program worked out by Dr. Theodore L. Dehne, Dr. Lauren H. Smith, and their colleagues on the Committee of Arrangements, and Dr. John Donnelly and his associates on the Program Committee. Special thanks are due the "Ladies" Committee, with Mrs. John Davis carrying forward their programs admirably. To Mr. Austin M. Davies, the Executive Assistant, Dr. Matthew Ross and Messrs. Robinson and Turgeon and the members of their staff who so courteously and faithfully worked to make this meeting successful, the Association continues indebted.

Lawrence C. Kolb, M.D.,
Secretary, *pro tempore*

HEALTH INSURANCE FOR PSYCHIATRIC PATIENTS

The need for group insurance to cover mental illness as well as the other types of disability that are already provided for in this way has been a matter of serious concern to organized psychiatry, and an experimental plan has now been announced whereby, through the generous cooperation of Group Health Insurance, Inc., an all inclusive coverage may become possible.

The three agencies sponsoring this project are The American Psychiatric Association, The National Association for Mental Health, and the National Institute of Mental Health. The latter, a federal agency, has authorized a grant of \$300,000 for a two-year experimental study. **Additional funds will be supplied by Group Health Insurance, Inc., a non-profit agency, as announced by Arthur H. Harlow, Jr., President of this organization.**

A substantial specified group of G. H. I.

subscribers is being selected with the collaboration of W. F. Dement, professor of statistics at the Graduate School of Business Administration, New York University, for the initial study. Unskilled and poorly skilled workers and their families will make up about half of this group, clerical personnel another 25 percent, skilled workers 17 percent, executives and professional persons 8 percent. Both inpatient and outpatient treatment within stated limits will be covered by the plan.

A committee composed of both psychiatrists and laymen and headed by Dr. Harvey J. Tompkins, Chairman of the New York City Community Mental Health Board and director of psychiatric services, St. Vincent's Hospital, will supervise this new project which marks a conspicuous milestone in the care and treatment of the mentally ill.

ETHICS IN BUSINESS

Late in December 1912 Pierpont Morgan was called to Washington to answer questions of a House Investigating Committee relative to an alleged "money trust" in the United States. Morgan's death three months later, aged 76, was probably hastened by that ordeal.

Q. Is not commercial credit based primarily upon money or property?

A. No sir; the first thing is character.

Q. Before money or property?

A. Before money or anything else. Money cannot buy it. . . . Because a man I do not trust could not get money from me or all the boards in Christendom.

—Quotations by FREDERICK LEWIS ALLEN in
The Great Pierpont Morgan.

CORRESPONDENCE

ROLE OF PSYCHIATRIST IN CRIMINAL TRIALS

Editor, THE AMERICAN JOURNAL OF PSYCHIATRY :

SIR : This is a brief comment on the article "Role of the Psychiatrist in Criminal Trials," by Joseph B. Cumming, in the American Journal of Psychiatry, 115 : 491, Dec. 1958.

I do not take exception to the author's defence of the M'Naghten rule or his doubts about the rule adopted in the case of *Durham v. U. S.*

The author may be criticized, however, for his repeated critical statements about psychiatry and psychiatrists, which he has not supported by a single reference. Here are a few examples :

We are urged, therefore, to give more heed to, if not to be guided entirely by, the opinion of expert witnesses testifying as to the accused's absence of criminal intent (p. 491).

We have been told that the M'Naghten rule is obsolete, being based on outmoded conceptions of human responsibility (p. 492).

The psychiatrists condemn this method of deciding the validity of such defense (p. 497).

The article may be criticized also, for the notion that the defence of insanity is an intimate war between doctors and lawyers, is an example :

May we find an impasse between the two professions that cannot be eliminated. . . the doctors must live with the Law as it is and as it will be changed and reinterpreted from time to time by the bench and bar (p. 496).

Surely the elected legislators have some part to play !

The subject has been treated more adequately by Professor Jerome Hall in his book, *Studies in Jurisprudence and Criminal Theory*. Professor Hall has taken his statements about psychiatrists, chapter and verse, from psychiatric journals and he asserts that more is involved than a contest between psychiatrists and lawyers.

K. G. Gray, Q.C., M.D.,
University of Toronto.

REPLY TO THE FOREGOING

Editor, THE AMERICAN JOURNAL OF PSYCHIATRY :

SIR : As requested in your letter of February 4, I am writing to reply to the letter received by you from K. G. Gray, Q.C., M.D., in which Dr. Gray has taken certain exceptions to the position which I took in my article "The Role of the Psychiatrist in Criminal Trials," published in the American Journal of Psychiatry, 115 : 491, Dec. 1958.

Dr. Gray comments adversely on what he calls my "repeated critical statements about psychiatry and psychiatrists, which he has not supported by a single reference." I do not consider that my comments were critical. I was dealing with a controversial subject, one side of which, in general, has been supported by the psychiatrists. This I think I can support by the references which Dr. Gray desires. They will be given later in

this communication. My comments were made on an assumption of an attitude taken by the psychiatrists. Such statements of mine to that effect may have been incorrect, but they were not critical. If my assumption is incorrect, then it would seem that my objection to that attitude would have no validity and, therefore, there is unanimity of views.

If I have correctly assumed the attitude of the psychiatrists toward the Durham rule in contradistinction to the M'Naghten rule, I feel that I am at liberty to point out wherein I believe the M'Naghten rule is the better of the two, without being guilty of the charge of being critical of either the men who hold a different view or of the discipline of which they are members. No practicing lawyer such as I am could possibly consider that he was antagonistic to

opposing counsel who held different views in a legal controversy. I have no more hostile attitude toward a psychiatrist who holds a different view than I have toward a brother lawyer who opposes me in litigation. In fact, rather than being critical of either psychiatry or its practitioners, I confess that I accorded them a deserved praise as I referred, on page 491, to "the great strides and revealing progress in psychiatry which there are now established the means of discovering the nature of man's mental processes, his motives and intents" (p. 491), and, again, when I wrote: "There is justified pride in the accomplishments of psychiatry. Its advancement in the diagnosis, treatment and cure of the mental diseases has brought light to those who sit in darkness" (p. 496).

Dr. Gray in his letter picks what he speaks of as a few examples of my critical attitude. These examples I consider merely an effort on my part to present the contentions of psychiatrists in their consideration of the M'Naghten rule. I undertook to defend the M'Naghten rule, and in order to do so I felt that it was proper for me to present the opposition to the M'Naghten rule, and also to present what I consider the position taken by the psychiatrists as to their ability to testify with reference to the mental condition of a person charged with a crime so that his culpability could be better understood. My effort to present this side of the case is what Dr. Gray considers to be critical of psychiatrists and psychiatry. I would like to quote from certain works on this subject, as Dr. Gray desires that I do, to support my position that most psychiatrists are in opposition to the M'Naghten rule and that they consider that the current method of ascertaining the guilt of a person charged with a crime is unsatisfactory.

Judge Bazelon's opinion (in the *Durham* case) has been hailed by psychiatrists everywhere as a noteworthy advance. This permits the psychiatric expert to think and function in his true professional capacity.

Manfred S. Guttmacher: Why Psychiatrists Do Not Like to Testify in Court, from *The Practical Lawyer*, 1: No. 5, May 1955.

Ten out of the thirty-eight States still follow that of Colburn's later amendment with the M'Naghten rule, and so, in the majority of mental illness as a possible cause for a criminal act. . . . The change was brought about by psychiatrists and I do not suppose that that it is a great improvement. . . . new modes of using psychiatric testimony in regard to criminal offenses.

Thomas S. Szasz: Psychiatric Expert Testimony: Its Current Meaning and Social Function, from *Psychiatry*: 20: No. 3, 313, Aug. 1957.

Psychiatrists who have advocated revisions of the M'Naghten rule have based their claims on the greater knowledge of human behavior gained during the past half century.

Ibid., p. 314.

We, as psychiatrists, are overly fond of taking on problems which we are incapable of treating effectively at the present time. This is particularly true in the field of criminology. The concept of free will in man who is a mentally responsible individual of society is the underlying basis of all criminal law; therefore, if we, as psychiatrists, promote a theory of psychiatry which denies this principle, we are undermining our legal system; thus the ultimate detrimental effect on society is inevitable.

Eric Bell, Jr.: The Basis of Effective Military Psychiatry, from *Dis. of the Nervous System*, 19: No. 7, July 1958.

Dissatisfaction with legal rules and the apparent reluctance of attorneys to modify trial rules and practices governing mental disease and criminal responsibility, amounts almost to a cold war between the two disciplines.

Walter Bromberg and Hervey M. Cleckley: The Medico-Legal Dilemma—A Suggested Solution, from *J. of Criminal Law, Criminology and Police Science of Northwestern University*, 42: No. 6, March-April, 1952.

Nevertheless, it seems to me that there is implicit belief in the minds of most psychiatrists interested in legal matters that the application of psychiatric knowledge to jurisprudence is bound to make the law more "human" and "just," rather than less so. This assumption should not be accepted at face value.

Thomas S. Szasz: Some Observations on the Relationship between Psychiatry and the Law, from *Arch. of Neurol. and Psychiat.*, 7: 298, Mar. 1956.

The methods of procedure are such that I usually leave the witness stand with the feeling that I have not done justice to the side for which I testified nor to the cause of truth nor to myself.

William Alanson White: *The Autobiography of a Purpose*, 192-193, 1938.

When they all individually and jointly (judges, lawyers, and jury) ask me whether the defendant in the dock is in my opinion insane, I must candidly state, if I am to remain true to my professional knowledge and faithful to my oath, first, that I do not understand the question, and, second, that since I don't understand the question, I do not know whether the defendant is insane or not. I admit the situation is embarrassing and puzzling to all concerned, but it is beyond my knowledge and power to remedy or alleviate it.

G. Zilboorg: *Mind, Medicine and Man*, N. Y.: Harcourt, Brace and Co., Inc., 1943.

We have reached a rather disquieting parting of the ways. This is undesirable from both your (the jurist's) point of view and mine. Your rules are unintelligible to me, and my inability to follow them is unintelligible to you.

Ibid. As quoted in *The Mask of Sanity*, Cleckley, St. Louis: C. V. Mosby Company, 1950.

A major underlying fact of the current polemics is the clash of elementary philosophical perspectives.

Jerome Hall: *Psychiatry and Criminal Responsibility*, *The Yale Law Journal*, 65: No. 6, May 1956.

Dr. Hervey M. Cleckley, the author of numerous papers on psychiatry, as well as certain published books (*The Mask of Sanity*, *The Caricature of Love*, and (co-author) *The Three Faces of Eve*), read my paper and wholly approves not only my assumptions as to the attitude of most psychiatrists but my statements as to their support of the Durham rule and antagonism toward the M'Naghten rule. He also supports my position in this controversy.

Dr. Gray's third criticism is that I consider that the defense of insanity "is a private war between doctors and lawyers." I believe the above quotations from Zilboorg, Cleckley, Hall and Szasz adequately support my assumption of the existence of

this conflict. You will recall that in the first draft of my article which I sent you I pointed out that there exist two opposing views on the question of the extent to which mental abnormality should relieve from responsibility for crime. After describing the two opposing views and their protagonists, I stated: "Most of the former are members of the Bar; most of the latter are psychiatrists." This quoted language and the immediately preceding language were stricken in the interest of brevity.

It is not a private war. Members of the Bar, because of their position as officers of the court and their responsibility as professional men in all matters affecting the administration of justice, represent the public interest in all such controversies in the administration of justice. By the same token, I felt free to regard the psychiatrists as the best equipped to speak of the advancements in psychiatry in a matter which made them critical of certain judicial processes. It is a public war, but the champions are those best equipped to represent the opposing sides.

I cannot view the controversy with the alarm that apparently disturbs Dr. Gray. It is through the exchange of opposing views that new ideas are developed. I had hoped that my paper would bring forth opposition to my contentions, since that would give me an opportunity to exchange views with any who took issue with my contentions as expressed in that paper. I have received many letters, which have included more than 50 requests for reprints. Each communication which expressed any views at all was complimentary. Dr. Gray's letter does not take issue with my views, but merely criticizes what he considers a critical attitude. He expressly says that he does not take issue with my defense of the M'Naghten rule. I am still to receive a challenge attacking my beliefs.

Dr. Gray, in conclusion, states: "Surely the elected legislators have some part to play!" I realize that Dr. Gray, being trained in the polity of the British Constitution, where there is not the separation of powers that exists under our system, might not appreciate the fact that the Legislature does not have the right to invade the Judiciary by telling the latter how it should conduct

the trial of cases. I recognize that this is done quite frequently, but there is a strong tendency to permit the Judiciary to handle its own affairs. Legal procedure is not primarily a function of legislative control under the doctrine of the separation of powers. Even if it were a legislative matter, public controversy touching the subject is, as in all such cases, essential to bring forth the strongest arguments for and against any legislative change.

I regret that I have had to answer Dr Gray's letter at such length when you requested a brief reply. You are at liberty to remove such portions as you consider superfluous, though I would like to have Dr Gray read my entire letter. If he wishes to do so, I would like to exchange views with him on the question.

Joseph B. Cunningham
Lecturer in Jurisprudence
Medical College of Georgia

A COMMENT ON "SWEDISH PSYCHIATRY"

Editor, THE AMERICAN JOURNAL
OF PSYCHIATRY:

SIR: In the December 1958 issue of this *Journal*, Prof. Kinberg has made some comments on Swedish psychiatry. As a psychiatrist from Sweden who sought advanced training in America, I feel it is important to correct the impression conveyed to American readers by Kinberg's article.

Kinberg has always tried to promote the Sjöbring view on psychiatry. This view can briefly be described as a magical belief in some kind of correspondence between psychical processes and central nervous system processes. Thus if the psychic processes are rapid, this means that the central nervous system processes are rapid; if a person has stable habits this means that the central nervous system facilitation is stable. If a person does not fit into Sjöbring's system he is said to have a lesion, e.g., in the form of an encephalitis. This is assumed to exist even with complete lack of clinical evidence. No empirical proof of the correctness of this brain mythology is offered, and none is needed according to Sjöbring, because introspection gives us sufficient knowledge regarding the processes in the central nervous system. No therapy can be built on the system, and psychical diseases become essentially untreatable except by the crudest methods. This may be enough to indicate to the reader the value of Sjöbring's speculations.

In his paper Kinberg states "... I followed with interest the publications of Freud as they appeared. When I learned by his '*Traumdeutung*' of foetuses that had been listening to the coition of their par-

ents I lost all interest in his extravagant phantasies" (p. 502). The passage Kinberg believes he is referring to must be the one found on page 399 in Freud's *The Interpretation of Dreams* (Vol. 5, Standard Edition, London, 1953): "A large number of dreams, often accompanied by anxiety and having as their content such subjects as passing through narrow spaces or being in water, are based upon *phantasies* of intra-uterine life, of existence in the womb and of the act of birth. What follows was the dream of a young man who, *in his imagination* (italics mine), had taken advantage of an intra-uterine opportunity of watching his parents copulating." The English version closely follows the original German text. This is only one example of a kind that abound in Kinberg's writings, illustrative of the degree of accuracy and fairness he uses when dealing with psychoanalysis.

Kinberg's statements about causality only being applicable to physical and mechanical happenings, his belief that psychoanalysis can be refuted on epistemological grounds, and his rejection of psychoanalysis as a science, are not valid. They probably rest on older philosophical writings imperfectly understood.

The European professor has an influence on the development of his specialty in his country that American readers can hardly imagine. Kinberg for many years successfully fought the use of the Rorschach Test in Swedish psychiatry, because it demonstrated such queer things in people whom he "knew" to be normal. In 1953, in some articles in the largest daily newspaper in

Sweden, he stated emphatically that dreams have no significance whatsoever, being merely the waste and rubbish of the all-important conscious process. In fact, he rejected the concept of the unconscious altogether. In these articles he reviewed a volume of *The Psychoanalytic Quarterly* (Zilboorg, Szasz, Friedman, Renneker, Roheim) with unfair demagoguery, attempting to ridicule his American colleagues before the lay public.

What can be inferred from Kinberg's paper is the fact that Swedish psychiatry is in a sad state. Kinberg and Sjöbring together are to a great extent responsible for the fact that only about ten psychiatrists in Sweden have had any training in psychotherapy. This means that thousands of men-

tally ill people in Sweden are not receiving adequate treatment, and much needless suffering is thus caused by the influence of these two men.

I have written this short note to indicate to American readers that some Swedish psychiatrists are aware that in Sweden psychiatry has not developed at the same rate as other medical specialties have. A few of us are seeking training at home and abroad in order eventually to try to change Swedish psychiatry, at present so barren and lacking in international contact, and to bring it to a level acceptable by modern standards.

Austen Riggs Center, Inc.,
Stockbridge, Mass.

REPLY TO THE FOREGOING

Editor, THE AMERICAN JOURNAL
OF PSYCHIATRY:

SIR: I decline discussing scientific psychiatric problems with anybody who considers the existing axiomatic correspondence between psychic processes and brain processes as "magical."

The short description of Sjöbring's important scientific findings and comprising psychologic and psychiatric theory is a caricature which I don't care to spend time on.

Dr. Löfgren's contention that Sjöbring and myself are "to a great extent responsible for the fact that only about ten psychiatrists in Sweden have had any training in

'psychotherapy,'" is a great compliment to us, if by "psychotherapy" is meant psychoanalysis. Of course psychotherapy, in its old medical sense, does exist in Sweden as in other civilized countries.

Some days ago I got several important reprints on psychoanalysis from Dr. Henry Turkel (Detroit), which appear to indicate that there is a strong movement on the North American continent against the superstitions called psychoanalysis.

NEWS AND NOTES

ASOCIACION PSIQUIATRICA DE LA AMERICA LATINA.—This new Association is a federation of the various psychiatric associations in the Latin American countries. Such an organization had been under discussion for several years and was finally constituted at a meeting in Lima, Peru, October 28, 1959.

The following countries are presently represented in the Association: Argentina, Brazil, Chile, Cuba, Equador, Mexico, Paraguay, Uruguay.

The objectives of the Latin American Association are to promote active exchange of information, to publish a common journal, to establish international co-operation, to organize Latin American psychiatric congresses, and to promote interrelations with other psychiatric associations throughout the world. The board of directors of the Association are: Dr. Gregorio Berman, Argentina; Dr. Pacheco E. Silva, Brazil; Dr. F. Falcón, Mexico; Dr. Carlos A. Seguin, Peru; Dr. José A. Bustamante, Cuba.

PATIENT'S BILL OF RIGHTS.—The National League for Nursing, at the opening of its biennial convention in Philadelphia, May 11, 1959, presented a "patient's bill of rights" which had been developed by more than 3,000 people meeting in hundreds of sessions throughout the country over the past two years.

The statement is a seven point "bill," as follows: The patient has a right to expect:

1. That he will receive the nursing care necessary to help him regain or maintain his maximum degree of health.

2. That the nursing personnel who care for him are qualified through education, experience and personality to carry out the services for which they are responsible.

3. That the nursing personnel caring for him will be sensitive to his feelings and responsive to his needs.

4. That, within the limits determined by his doctor, the patient and his family will be taught about his illness so that the pa-

tient can help himself, and his family can understand and help him.

5. That plans will be made with him and his family, or if necessary for him, so that, if possible, continuing nursing and other necessary services will be available to him throughout the period of his need. These plans will involve the use of all appropriate personnel and community resources.

6. That nursing personnel will assist in keeping adequate records and reports and will treat with confidence all personal matters that relate to the patient.

7. That efforts will be made by nursing personnel to adjust the surroundings of the patient so as to help him maintain or recover his health.

ILLINOIS PSYCHIATRIC SOCIETY.—On April 15, 1959, the following members of the Illinois Psychiatric Society were elected to office for the year 1959-60: president: Dr. Frances Hannett; president elect: Dr. Joel S. Handler; secretary-treasurer: Dr. Paul E. Nielson; councillors: Dr. Nathaniel S. Apter and Dr. C. Knight Aldrich.

Serving their 3rd year of a 3-year term are Delegate to American Psychiatric Association Assembly: Dr. John R. Adams, and Alternate Delegate, Dr. Isadore Spinks.

SURVEY OF SALARIES IN PSYCHIATRIC CLINICS AND HOSPITALS.—The Des Moines Child Guidance Center has completed "A Salary Survey of Salaries for Professional Positions in Psychiatric Clinics and Hospitals (1959)." Based on a nation-wide sample, the study describes salary levels and ranges in relation to training and experience requirements. The report includes comparisons based on the Center's 1955 study, showing the nature of shifts in salary levels in the intervening 3-year period.

To obtain this pamphlet write to Des Moines Child Guidance Center, 500 Garver Building, Des Moines 9, Iowa. Price, single copy, 25c; 10 or more copies, 15c each.

DEATH OF DR. DEJARNETTE.—A delayed report of the death, at the age of 90, of Dr.

Joseph Spencer DeJarnette of Staunton, Va., recalls the significant part he played in Virginia psychiatry. Graduating from the Medical College of Virginia in 1888, he joined the staff of Western State Hospital, Staunton, in 1889 and later became superintendent. He was also founder and superintendent of the DeJarnette Sanatorium, and he was instrumental in the founding of the Lynchburg Training School and Hospital at Colony, Va., of which he was the first superintendent.

Through his efforts the Virginia Sterilization Law was enacted in 1924. This was the first sterilization law to pass the Court of Appeals of the United States.

Dr. DeJarnette had served as president of the Augusta County Medical Society and of the Medical Society of Virginia. He was a life Fellow of The American Psychiatric Association of which he had become a member in 1909.

THE DEVEREUX DINNER PROGRAM.—This annual feature of Convention Week, generously provided by the Devereux Schools, was held Monday evening, April 27 at the Benjamin Franklin Hotel, Philadelphia. The capacity of the ball-room was taxed by the dinner guests of Miss Devereux and her staff, and following the banquet entertainment was provided by well trained groups of students from the various classes of the Schools. There were songs, dances and marches and highly amusing numbers reminiscent of the old minstrel show days that did credit to the performers and rounded out a delightful evening preparatory to the strenuous days and evenings to follow.

DR. CAMERON HONORED.—The Postgraduate Center for Psychotherapy, New York City, which offers the Ruben award annually for outstanding achievements in mental health, presented the award for 1959 to Dr. D. Ewen Cameron. At the presentation made in New York City on April 17, 1959, Dr. Cameron was cited for "the tremendous contributions you have made in research and as a teacher in the field of psychiatry."

THE PROBLEM OF STUTTERING.—Wendell Johnson, Ph.D., professor of speech pathol-

ogy and psychology at the University of Iowa, himself a former stutterer, has written a booklet *Toward Understanding Stuttering*, published by the National Society for Crippled Children and Adults.

Written especially for parents, the 40-page publication is a revealing study of more than 25 years of extensive and intensive research in stuttering problems.

Copies may be obtained by writing the Easter Seal Society, 2023 West Ogden Ave., Chicago 12, Ill. Price, 25c.

DR. WILLIAM CONE DIES.—With the death of Dr. William Cone of Montreal, May 4, 1959, Canada lost one of her most eminent neurosurgeons. His age was 62. A native of Iowa, he came to Montreal in 1928 to join the staff of Dr. Wilder Penfield at the Neurological Institute of McGill University, and rapidly advanced to the post of professor of neurosurgery. He was also associate professor of neuropathology.

In World War II Dr. Cone was one of the first Canadian medical men to go overseas. He and Col. Colin Russell organized the No. 1 Canadian Neurological Hospital and he served that institution as chief neurosurgeon.

In Montreal he established a helicopter delivery service whereby patients could be landed on the McGill University football field close to the Neurological Institute in order to secure the quickest possible treatment in emergency neurosurgical cases.

Dr. Cone was devoid of self-consideration in his devotion to his work. He was preeminent as an operator and innovator and teacher.

SOUTHERN REGIONAL EDUCATION BOARD GRANTS TO MENTAL HOSPITAL PERSONNEL.—Grants have been awarded since June 1958 to enable employees of mental hospitals and training schools in the Southern region to study care and treatment in institutions anywhere in the country. Awards up to \$500 are made to cover expenses for a period of 4 weeks or less. Grantees have gone to many different institutions in 22 states and Canada. Florida, 3 grants; Kentucky, 9; Louisiana, 10; Maryland, 5; North Carolina, 15; Oklahoma, 16; South

Carolina, 5; Tennessee, 2; Texas, 16; Virginia, 18; West Virginia, 1.

Funds for the two-year grant program were provided to the SREB by the National Institute of Mental Health. Applications are being accepted until June, 1960. For further information write to Dr. Penningroth, Southern Regional Education Board, 130 Sixth St., N.W., Atlanta 13, Ga.

WHITNEY M. YOUNG, JR. RECEIVES HIGH SOCIAL WORK AWARD.—Whitney M. Young, Jr., Dean of the Atlanta University School of Social Work, Atlanta, Georgia, received the 1959 Florina Lasker Award from Clara A. Kaiser, Chairman of the Award Committee.

The award of \$1,000 and a scroll noting the outstanding welfare accomplishments of Mr. Young were made at the National Conference on Social Welfare, held in San Francisco, May 24-29.

Mr. Young's "vigorous, wise and unafraid leadership" in the field of desegregation and civil rights for Negroes was cited by Dean Kaiser as a factor in the Committee's decision to honor him.

AWARD TO DR. GREENACRE.—Phyllis Greenacre, M.D., New York City psychoanalyst and clinical professor of psychiatry at Cornell University School of Medicine has received the 1959 Charles Frederick Menninger Award of the American Psychoanalytic Association. The Award is given annually for outstanding contributions to the theory and practice of psychoanalysis. Dr. Greenacre is known particularly for her psychoanalytic interpretations of Jonathan Swift, Thomas Mann, and Lewis Carroll. She has also made important contributions to the understanding of child and personality development. The Award is named in memory of the father of Doctors Karl A. and William C. Menninger, the well known psychoanalysts of Topeka, Kansas.

TRANSACTIONS OF THE FIFTH ANNUAL MEETING OF THE ACADEMY OF PSYCHOSOMATIC MEDICINE.—Transactions of this meeting titled, "The Psychosomatic Aspects of Internal Medicine," are available from

Dr. Wilfred Dorfman, 1921 N. 4th Ave., Brooklyn 26, N. Y., at \$3.00 per copy.

KEINISCH PSYCHOATHOLOGIE. The author of this book (Prof. Kurt Schneider, Heidelberg), reviewed in an earlier edition, *Am J Psychiatry*, p. 256, Sept. 1958, is now brought out a fifth revised edition, 1959, published by Georg Thieme Verlag, Stuttgart.

It is an excellent guide in concise form, the text running to only 161 pages.

ASSOCIATION FOR RESEARCH IN NERVOUS AND MENTAL DISEASE, INC. The annual meeting of the Association for Research in Nervous and Mental Disease will be held on December 11-12, 1959, at the Hotel Roosevelt, New York City. The subject of the meeting will be "Mental Retardation."

For further information write: Dr. Rollo J. Mueselink, Secretary-Treasurer, 700 West 168th St., New York 32, N. Y.

MILBANK MEMORIAL FUND.—The Milbank Memorial Fund has published a 104 page brochure of the proceedings of its 34th annual conference, 1957, Part II, entitled "Planning Evaluations of Mental Health Programs." It contains a progress report of the Evaluation Planning Groups' efforts to identify specific types of mental health programs which might lead to reductions in the amount of specific mental disorders, and the proposal of a Model for a project to prevent mental disorders in an aged population. The book also contains a synthesis of the discussions and suggestions, by Conference members of the proposed Model.

The book may be obtained from The Milbank Memorial Fund, New York. Price, \$1.00.

ADOLF MEYER MEMORIAL AWARD.—Dr. Herman B. Snow has been designated this year to receive the Adolf Meyer Memorial award for his outstanding work as director of St. Lawrence State Hospital in respect to the development of the open door policy.

The presentation was made at special ceremonies held at the New York Academy of Medicine in New York City, May 2, 1959.

BOOK REVIEWS

NEUROPHARMACOLOGY: TRANSACTIONS OF THE SECOND CONFERENCE. Edited by *Harold A. Abramson*. (New York: Josiah Macy, Jr. Foundation Publication, 1956, pp. 308. \$4.25.)

The transactions of the second conference on neuropharmacology of the Josiah Macy, Jr. Foundation consists of records of five discussions, each one led by an invited discussant and joined in by the rest of the invited group in accordance with the usual procedures of these conferences. Aurelio Cerletti analyzed the effects of LSD, chiefly on animals, its ability to evoke a rise of temperature and other signs of autonomic stimulation such as dilatation of pupils, piloerection, salivation, lacrimation. In addition, ataxia and paresis are produced. Though the accompanying anxiety may be secondary to the physical state, yet the use of chlorpromazine can suspend the anxiety part of the syndrome, but not the neurological aspects. BOL, a brom derivative of LSD, does not bring on hallucinations yet it blocks serotonin actively even more strongly than does LSD. Stephen Sherwood's presentation is concerned chiefly with behavioral effects following intraventricular injection of drugs into animals and man. These results may be attributed to structures in the lining of the third ventricle. The injection of cholinesterase improves psychotic patients and also exerts a good effect on the thought processes. Banthine also makes patients more active but has little effect on these thought processes. It is clear that direct injection of substances into the ventricle opens a new method of attack in this field, but the results are not always the same as those of peripheral injection. Humphry Osmond gives a delightful talk on work in which he was not only an observer but also an experimental subject and could, therefore, speak both from objective and subjective viewpoints. He presents the development of the ideas which induced his group, including Hoffer and Smythies, to study the effects of psychotomimetic drugs: their ability to produce changes in thinking, mood and perception. It was emphasized that these alterations are different from the toxic confusional illnesses characterized by unawareness of the immediate environment. It is realized, however, that there is a continuum between the two types of mental disturbances. Max Rinkel presents chiefly a review of work in which he was associated. Studies of behavior in 43 normals

showed that LSD tended to evoke hostility, withdrawal, and desire for reassurance. An interesting analysis is made of the productions of a painter before and at various periods after the administration of LSD. The drawings showed a progressive, almost schizophrenic-like deterioration. The changes in the thought processes, mood and perception are thus graphically presented. The last discussion was led by Harold Abramson, who stresses the rapid development of tolerance to LSD, and that LSD given repeatedly is its own best antidote. On the basis of these observations, he presents the hypothesis on the mechanism of schizophrenia, namely: 1. That there is a substance analogous to LSD involved in schizophrenia which he designates as P; 2. That P has some normal function in the physiology of the emotional processes but the metabolism of P is disturbed by schizophrenia; and 3. That the substance P is regulated by a mechanism similar to that for the development and loss of tolerance to LSD. Taken altogether, we have in this book a compendium of views of investigators from many different fields, all focused on problems concerned with the relation of psychotomimetic drugs to behavior. It is a welcome addition to our library.

H. E. HIMWICH, M.D.,
Galesburg, Ill.

METHODOLOGY OF THE STUDY OF AGEING. Ciba Foundation Colloquia on Ageing. Vol. 3. (Boston: Little, Brown and Co., 1957, pp. 202. \$6.50.)

This book, a series of papers by extremely well qualified persons, reports some observations of studies made on ageing and the techniques to be used for further research on this problem. A few samples will give some idea of the interesting and speculative material presented.

In the first chapter, A. Comfort attacks the theories of senescence which base the loss of vigor in old age on "a single 'fundamental' or 'inherent' cellular, chemical, or mystical process common to all multicellular animals, contrasting with the extremely ill-named 'immortality' of protozoa . . ." The pattern of senescence may differ much in various mammals, and it is still to be determined whether all vertebrates undergo senescence.

François Bourliere discusses functional age changes and the fact of physiologic differences in the ageing of various kinds of animals

and senescence as a fundamental characteristic of animals. He considers it highly significant "that these mammals which have a poor temperature regulation and a normally low rate of metabolism are precisely those whose life-span is far longer than that of other mammals of similar size." He also reports observations showing that a low calorie diet may increase the life span.

F. Verzar points to a number of changes "of the proteins of cells and tissues which lead to the decreased capacity of the aged individual to adapt himself to the constant changes in conditions of life." He also considers the "continuously increasing capacity of the tissues to bind calcium" as possibly due to defects in protein metabolism.

This book should be read by all students of gerontology.

K. M. B.

GENERAL TECHNIQUES OF HYPNOTISM. By André M. Weitzenhoffer. (New York: Grune and Stratton, 1957, pp. 460. \$11.50.)

The general techniques referred to in the title of this book pertain to those associated with production of hypnotic phenomena in general. As the author who is a psychologist states, these contrast with specialized techniques relevant to certain fields of application, such as psychiatry. Coverage is broad, but the book is too long and detailed. A major aim is to offer the student a "working understanding of hypnosis and hypnotic phenomena." Extensive inclusions incorporate data from scientific, quasi-scientific and non-scientific sources. The experienced clinician or investigator should be able to judge these sources and, of course, he has less need for this volume. The novice would have difficulty in differentiating relative merits of material included, yet he would be expected to benefit most. The book, nevertheless, can be useful to the new student provided he can become more firmly grounded in his area of practice by participation in high quality courses of instruction and by reading specialized textbooks. The experienced practitioner may find this volume helpful as a supplementary source of reference in his hypnosis library.

JEROME M. SCHNECK, M.D.,
State University of New York,
College of Medicine, New York City.

SIX CHILDREN. By Estelle J. Foote, M.D. (Springfield, Ill.: Charles C Thomas, 1956, pp. 317.)

The writer accounts for her work as psychiatrist in a traveling school clinic for a period

of 9 years. Presentation of her chapters on the "Quick thinking child," the "Slow thinking child," the "Child whose brain has been injured," the "Child maladjusted emotionally," the "Child of unusual cultural background" and the "Child of unusual training" is not in keeping with scientific principles since the writer does not support her many claims and conclusions with statistical evidence. The experienced reader will find it difficult to accept the many generalizations offered. The chapter on the brain-injured child lacks a definition of "brain injury." One wonders whether the "quick thinking" child has a mental capacity within the upper range of normal variations of human intelligence, or has a superior intelligence, or is of the genius classification of intelligence. Many readers will find the chapter on the "maladjusted child" confusing since no definition is offered. "Maladjustment" seems to include all neuroses and even psychoses. Psychometric tests are not defined. However, it seems that only the Stanford-Binet test has been applied. Psychodiagnostic techniques are not mentioned at all. The psychiatric approach is descriptive. The bibliography is very spotty with emphasis on publications 30 years old. The book has historic value.

PETER W. BOWMAN, M.D.,
Powder, Me

THE ORGANIC PSYCHOSES: A GUIDE TO DIAGNOSIS. By John G. Deegan and William B. Spaulding. (Toronto: University of Toronto Press, 1958, pp. 170. \$5.95.)

In his foreword Doctor Aldwyn Stokes sets the tone for this book when he notes that sometimes in clinical psychiatric practice it appears as if the problems of organic psychoses have been "given up" rather than "taken up." Unfortunately, this statement is all too true, as many hospital officials will testify. Seemingly, the designation "organic" in many instances brings with it a loss of interest, particularly in the young clinician. To be organically mentally ill, what is it but to be organically mentally ill?, to paraphrase the Bard.

It was in order to unravel some of the problems which the organic mental illness presents, that this small monograph was written. The authors, in undertaking the task, stress the fact that they have no intention of minimizing the role of the psychological or social forces in mental illness and they pay due homage to both of these. Parts I and II of the work describe briefly the illness from an etiological standpoint and set forth the distinguishing laboratory and clinical features. The information presented in these chapters is not exhaustive

and it makes no pretense to be all-encompassing. Where further details would be required, satisfactory references to various textbooks and journals are enumerated.

Part III of the volume elaborates the various practical applications to clinical cases. Beginning with a discussion of the clinical investigative approach and elaborating upon the diagnostic orientation, there follows a consideration of delirium, dementia, and then a discussion of functional mental illness associated with physical disease involving the brain.

The last chapter enumerates the various technical procedures necessary, the specimens required, the tests and the norms to be looked for.

In general, the book accomplishes its stated purpose as a guide to the diagnosis of organic psychoses. It should be a useful addition to the library of the student, the resident, the psychiatrist and the internist.

FRANCIS J. BRACELAND, M.D.,
Hartford, Conn.

THE GUILTY AND THE INNOCENT. My Fifty Years at the Old Bailey. By William Bixley. (New York: Philosophical Library, Inc. Aberdeen: The Central Press, 1958. pp. 176 + ill. \$6.00.)

The author of this book was for 50 years a supervisory official of the Central Criminal Court in London. After his retirement in June 1956, he decided to give an account of what he had seen and heard in that famous criminal court during the past half-century.

But before doing so he outlines the history of the Old Bailey and of that western corner of London where for centuries past justice had been dispensed. Here stands the present Central Criminal Court which dates from 1834. Included in this description the author gives examples of the horrid and barbarous punishments of the old days—hanging, drawing and quartering, boiling alive, cutting off the hands, branding, slitting the nose, pressing to death. Judge Jeffreys sentenced Titus Oates to 2,000 lashes, during the last few hundred of which the prisoner was unconscious.

The author also describes the infamous racketeering by the keepers for supplying "prisoners' comforts," a euphemism for "bare necessities" which could not be obtained if the prisoner had no money.

All these barbarities and abuses were before the days of Elizabeth Fry and Queen Victoria.

After giving some account of notorious Old Bailey criminals before his time—Captain Kidd

(whom he rechristens James although he was William), Jonathan Wild, Earl Ferrers—the author devotes the remainder of the book to his observations, recorded more or less sketchily but including considerable detail, of notorious prisoners he had known. These included Dr. Crippen (at whose trial the forensic expert Dr. Spilsbury began his notable career), William Joyce (Lord Haw Haw), Klaus Fuchs (atom bomb spy who got off much too easily), Neville Heath (sex pervert-murderer), Ronald True (drug addict, murderer, sentenced to death but reprieved as insane and sent to Broadmoor), and numerous others.

The author takes us through a veritable chamber of horrors, and then apologetically explains that he has displayed "only a minute fraction" of the cases he could have reported from his fifty years at the Old Bailey.

An index would greatly increase the usefulness of this book.

C.B.F.

DREAMS AND THE USES OF REGRESSION. By Bertram D. Lewin, M.D. (New York: International Univ. Press, 1958. \$2.00.)

It is a pleasure for every student of dream-psychology and of the history of science to read this small book. It was written by the most skilful and—*horrible dictu*—most intuitive among the now living workers in the field of the science and art of the interpretation and theory of dreams.

Besides the 1957 Freud Anniversary Lecture with the above title delivered by Dr. Lewin before the New York Psychoanalytic Institute, this small volume contains a list of all Freud Anniversary Lectures since their inception in 1951, a biographical note on Dr. Lewin, and a list of his publications from 1926 to 1955 numbering 36.

The title is thus phrased to recall Ernst Kris who first coined the term "Regression in the Service of the Ego." The author's aim is to show that the dualistic view of Descartes, his distinction between the observing mind, "*res cogitans*," and the observed world, "*res extensa*," corresponds to what we find in an "ordinary well-projected dream." At the beginning of scientific thinking Heracleitos around 500 B.C. "repudiated the dream." He recognized that in the dream we turn away from reality into a world of our own, that what we perceive in dreams, is not a reality. If we want to correctly observe reality we must eliminate as object of observation not only dream consciousness, but also the waking consciousness from our thinking. This view has since been held valid by scientists as most recently con-

firmed, among others, by Schroedinger.

It then seems paradoxical at first sight when we have to admit that Descartes was most decidedly influenced in forming his theories by three dreams he dreamed on the night of November 10, 1619. It seems strange that a dream experience may have determined his view of the world. As Lewin puts it: "The stone the builders rejected may have become the cornerstone." Those dreams were conceived by Descartes to be of divine origin. He believed that the Angel of Truth had descended upon him and confirmed his newly developed hypothesis that the physical world can be completely formulated in mathematical terms, a scientific conception of overwhelming import.

The author gives some general observations about different types of dreams which are of special interest to analysts. He gradually leads up to the conclusion which he finds corroborated by P. Federn's ideas on the role of the ego in dreams ("mental ego feeling"): that in dreams which successfully fulfill their function of protecting sleep the dreamer's role corresponds exactly to Descartes' "res cogitans." The dreamer is just an observer. Whatever is disturbing his sleep he succeeds in projecting into the outside. His own body feeling is eliminated, he stands as "res cogitans" against the outside world, the "res extensa," which includes his projected body feelings.

This is demonstrated by the report of Descartes' three dreams, the first two of which were failures as far as the protective function of the dream is concerned. Finally Descartes succeeds and falls into tranquil sleep. The author conjectures, and well might convince the reader, that the bodily disturbance in this case was "in some sort related to migraine or a convulsive condition."

The subtleties and details of the dreams and of Lewin's interpretations cannot, of course, be given here. These finesses have to be read and studied carefully to be appreciated and enjoyed.

The paper abounds in brilliant and interesting ideas which surround its main body like delightful embroidery and testify to the broad scholarship and esprit of the author. To publish this lecture in book form fits it as a proper setting fits a gem.

In parenthesis: It is gratifying to find the correct spelling "scopophilia" used here, a rare event in psychoanalytic publications. While it may appear picayunish to mention this, to this reviewer it conveys the feeling that the author really knows what the words he uses mean and where they come from. It would have been

even more gratifying if the name of the psychoanalyst, Dr. Theodor Reik, were spelled correctly, too.

JENNIFER LEWY, M.D.
LEWIS A. LEWY, CLINICAL

HERMAPHRODITISM, GENITAL ANOMALIES AND RELATED ENDOCRINE DISORDERS. By Howard W. Jones, Jr. and William W. Scott. (Baltimore: Williams & Wilkins, 1958. pp. 456. \$16.00.)

This is the most valuable monograph on its subject since the appearance of Hugh Houghton Young's now classic monograph in 1915, *Genital Abnormalities, Hermaphroditism and Related Adrenal Disorders*. In the 24 years which have elapsed since that remarkable work, much progress has been made in the understanding of the etiology and treatment of abnormalities of sexual development. Much new light has been thrown on the factors controlling sex differentiation. The determination of chromosomal sex has become an important means of finally answering questions as to genetic sex. There have been many advances in biochemistry which have helped toward the better understanding and treatment of such conditions as the adrenogenital syndrome, and not least the psychological understanding of psychosexual orientation, its growth and development has assisted to advance the treatment of disorders of sex.

There is an excellent first chapter on "The origin of the concept of hermaphroditism in Greco-Roman Culture," which is most interestingly illustrated with Greek and Roman works of art. Chapter 2, by Alfred Jost on "Embryonic sexual differentiation, embryology, physiology, abnormalities," is a short statement of the facts of embryological and genetic development with the emphasis on the endocrine regulation of sexual development. Chapter 3, by the senior author, deals with "The Criteria of Sex. The nomenclature and classification of hermaphroditism," and the remainder of the book deals with literally every aspect of the subject in a clear and authoritative manner. Every surgical corrective and exploratory procedure is abundantly and clearly illustrated. In Chapter 6, Harry F. Klinefelter gives a description of Klinefelter's Syndrome, brought up to date. This condition is a most interesting end-effect of embryonic eccentric development, upon which recent discoveries in cytology have thrown a critical light. In Chapter 21 John Eager Howard with the assistance of Claude J. Migeon, illuminatingly discuss "Cushing's Syndrome," and in

Chapter 22 John G. McAtee discusses "The radiological diagnosis of adrenal tumors."

There are 18 pages of references in double-column; a most splendid and detailed index of case reports; and a good subject-index concludes this admirable book.

MENTAL SYMPTOMS IN TEMPORAL LOBE EPILEPSY AND TEMPORAL LOBE GLIOMAS. By *Torsten Bingley*. (Copenhagen: Ejnar Munksgaard, 1958. pp. 151.)

This is a statistical study of 90 cases of temporal lobe epilepsy and 253 cases of temporal lobe gliomas from the Serafimerlasarettet, Stockholm. Dr. Bingley is consultant in psychiatry and psychology in the neurosurgical clinic of this hospital. His series consists of consecutive temporal lobe tumors in patients over the age of 10 from Prof. Olivecrona's service during an 11 year period. The cases of temporal lobe epilepsy were patients admitted to the hospital with a diagnosis of epilepsy—any type—over a 3 year period in whom an EEG focus was found in the anterior part of one or both temporal lobes; 16 of these were subsequently found to have gliomas. Most of the work that is presented concerns the epileptic group. All were examined psychiatrically by Dr. Bingley and psychologically by either him or the clinic's psychologist. The psychiatric evaluations are expressed in relatively simple and not "psycho-dynamic" (the quotes are the author's) terms. The psychological tests are directed at measuring attention and concentration, memory, intelligence, and cognition.

The presentation of the author's own work and his discussion about it actually constitutes less than a third of the entire text. Most of the remaining manuscript is given over to an historical and critical review of the various topics: concept of temporal lobes epilepsy, handedness and brainedness, mental symptoms of temporal lobe tumors, ictal mental symptoms in temporal lobe epilepsy, and inter-ictal symptoms in temporal lobe epilepsy. The author attempts to define as accurately as possible the various factors he has studied. It is in this connection that he delves at considerable length into the subject of handedness and brainedness.

There are a number of facets to his conclusions which he summarizes quite well. In essence, he found: 1. The most common mental syndrome of tumors of the dominant temporal lobe is emotional bunting (this may be

independent of any aphasia or increased intracranial pressure) whereas in non-tumorous cases, particularly where there is a bilaterally shifting EEG focus, the most prominent personality change is an "ixophrenic" syndrome characterized by mental "adhesiveness" and sometimes associated with paranoid trends; 2. Both verbal and non-verbal impairment occurs in dominant lobe lesions and in lesions with bilateral shifting EEG foci but not in recessive lobe lesions.

The author really provides no new information although he adds considerable support to certain ideas that others have arrived at with less rigorous methods. His approach to his topics is commendable and this alone makes the monograph worth reading. It is unfortunate that no projective techniques were employed; these may well have added quantifiable data concerning certain psychological aspects of epilepsy and temporal lobe disease which have been commented upon by others but actually have been quite poorly studied.

To this reviewer, the most interesting aspect of this monograph is the historical and critical (sometimes a little harsh) reviews of the various subjects. Though not always complete, they touch upon most of the main points, are concise and well thought out; they certainly emphasize the large amount of non-critical work that has been published in these fields.

THE BRAIN AND HUMAN BEHAVIOR. Edited by *H. C. Solomon, S. Cobb, and W. Penfield*. (Baltimore: Williams & Wilkins, 1958, pp. 564. \$15.00.)

This volume reports the proceedings of the Association for Research in Nervous and Mental Disease held at New York December 1956. The high standards of the preceding 35 volumes of the Association are maintained in its 36th. The subject, as the trustees of the Association realized, was a very broad one, and it was therefore wisely decided to limit its discussion to a consideration of the separate areas of the brain from the standpoint of our knowledge of these areas in relation to behavior. Each paper is followed by the report of its discussion. The papers represented are as follows: Lashley, Cerebral Organization and Behavior. Greenblatt & Solomon, Studies of Lobotomy. Denny-Brown & Chambers, The Parietal Lobe and Behavior. Bruner, Neural Mechanisms in Perception. Lacey and Lacey, The Relationship of Resting Autonomic Cyclic Activity to Motor Impulsivity. Penfield, Func-

tional Localization in Temporal and Deep Sylvian Areas. Bickford, *et al.*, Changes in Memory Function Produced By Electrical Stimulation of the Temporal Lobe in Man. Miller, Psychological Defects Produced by Temporal Lobe Excision. Chapman, Studies of the Periamygdaloid Area in Relation to Human Behavior. Gibbs, Abnormal Electrical Activity in the Temporal Regions and its Relationship to Abnormalities of Behavior. Green, *et al.*, Behavior Changes Following Radical Temporal Excision in the Treatment of Focal Epilepsy. Jasper and Rasmussen, Studies of Clinical and Electrical Responses to Deep Temporal Stimulation in Men With Some Considerations of Functional Anatomy. Hoch, Psychoses Producing and Psychoses-Relieving Drugs. Evarts, Neurophysiological Correlates of Pharmacologically Induced Behavioral Disturbances. Woolley, Serotonin in Mental Disorders. Feldberg, Behavioral Changes in the Cat after Injection of Drugs into the Cerebral Ventricle. Bremer, Physiology of the Corpus Callosum. Roberts, Functional Plasticity in Cortical Speech Areas and the Integration of Speech. Nielson, Cerebral Localization and the Psychoses. Halstead, Some Behavioral Aspects of Partial Temporal Lobectomy in Man. Wolff *et al.*, Highest Integrative Functions in Man During Stress.

EXTERNAL COLLIMATION DETECTION OF INTRACRANIAL NEOPLASIA WITH UNSTABLE NUCLIDES. By G. M. Shy, R. B. Bradley, and W. B. Mathews, Jr. (Baltimore: Williams & Wilkins Co., 1958, pp. 144. \$7.00.)

This is a report of 18 months' experience and 179 scans done at the National Institutes of Health. The first part of the monograph is essentially a manual which describes the authors' search for various types of collimators, the rather detailed characteristics of their apparatus and matters concerning the choice of an isotope. The tenor varies from a technical discussion to a very basic outline of which dial to turn when. The second portion of the monograph discusses some of the clinical aspects of this examination; this includes topics dealing with the characteristics of both the normal scan and scans in cases of tumors in various locations as well as other types of pathology e.g. carotid artery thrombosis, abscess.

The authors reach the conclusion "... that this technique approaches the usefulness of air contrast studies ... (but has the additional

advantages of ...). The monograph is a pleasant introduction to the subject of the localization of intracranial lesions. The authors discuss the physical properties of isotopes, the properties of collimators, and the properties of the brain in response to the scan. The monograph is a pleasant introduction to the subject of the localization of intracranial lesions and it is of interest to those working in the field.

This monograph is not a product of a systematic examination of the literature, but it is of interest to those working in the field.

W. J. FRIDLANDER, M.D.
Boston, Mass.

REHABILITATION: A COMMUNITY CHALLENGE.
By W. Scott Allan. (New York: John Wiley and Son, 1958, pp. 247. \$5.75.)

This book has value for the general reader, the student, and also for the professional worker in the field of rehabilitation. The author's aim is to stimulate individual or community thought and action toward more realistic and effective rehabilitation services. On the whole it has a humanitarian and perhaps somewhat of a utopian flavor. Nevertheless to contribute to the development of a society of justice, health, opportunity and security are basic, and fundamental toward which all men aspire.

The book comprises a total of 247 pages including more than 370 bibliographic references. The foreword, contributed by Dean W. Roberts, M.D., Executive Director for Crippled Children and Adults, points to the present day necessity for marshalling and integrating local resources, not only for ministering to the needs in the rehabilitation fields, but for an appropriate local level orientation to the subject matter.

This view is substantiated and enlarged upon by the author's discussion of the responsibilities of a community in planning, acting, and supporting measures for the rehabilitation of the handicapped and disabled. He gives consideration to the developing concepts of an interdisciplinary approach to rehabilitation; to the nature and availability of facilities and personnel; to budgetary sampling, to staff patterning, and to cash experiences.

He includes also a discussion of the impact which social laws, health insurance, medical care plans, social legislation, workmen's compensation benefits, and pre-paid health insurance may have upon the ultimate pro-

ductivity and welfare of the injured, handicapped and disabled. The closing chapter deals with various areas of challenge that may serve as "guide lines" for future plans and action in the broad field of rehabilitation.

W. L. T.

THE NEUROSES AND THEIR TREATMENT. Edited by Edward Podolsky, M.D. (New York: Philosophical Library, Inc., 1958. pp. 555. \$10.00.)

In this volume of 37 papers by various authors, Dr. Podolsky places side by side greatly differing attitudes and approaches. The articles range from the immediate and pragmatic to the speculative and hypothetical, bearing in mind that pragmatism for one reader is speculation for the next. There are included papers on infancy and childhood, adult neuroses, psychosomatic illnesses, problems of occupational neurosis, aging, post-partum anxiety states. Several papers discuss diagnostic issues, many involve aspects of psychotherapy, while 8 are devoted to treatment by drugs, carbon dioxide, and lobotomy.

Owing to the differences among the articles themselves, it is impossible to offer general statements about the subject matter presented. A number of authors do give the impression that they regard neurosis as a discrete entity which can be delineated in classical medical terms, subject to a "course," a "natural history." In his foreword, the editor states, "Neuroses are essentially conditioned anxiety reactions. Their emergence is automatic once they have been conditioned. They persist until the conditioning has been overcome by relevant emotional retraining processes."

One regrets the absence of papers especially devoted to the concept of neurosis *per se*, of anxiety, the role of anxiety in emotional growth and character formation as well as its role in growth deviations, the concept of need for object relationships, the use of symptoms to maintain such relationships. These areas are dealt with to a certain extent in several articles, such as Spitz's two papers on infancy, and in the fascinating report of "The Psychoanalysis of a Case of 'Grand Hysteria of Charcot' in a Girl of Fifteen," by Dr. Lydia G. Dawes; the concept of object relationships and the reaction to primary object loss (loss of "self") is implied in Dr. Shands' noteworthy study of cancer patients, "An Outline of the Process of Recovery from Severe Trauma."

The Neuroses and their Treatment is apparently designed for the "physician in active

practice." This reviewer believes that many of the articles are either too technical in language or too experimental in content to be readily assimilated into the non-psychiatric physician's practice. Derived from a number of psychiatric and medical journals, the articles do not have their formerly appended bibliographies, nor are there complete bibliographic citations to the original articles themselves. There is no index.

ALBERT FEINGOLD, M.D.,
Mass. Mental Health Center

MUSIK IN DER MEDIZIN. Beitrage zur Musiktherapie. Edited by H. R. Teirich, M.D. (Stuttgart, Germany: Gustav Fischer Verlag, 1958, pp. 199. DM 22,—.)

This anthology is divided into 4 parts, informally and without special designation or headings. However, by the contents of the contributions, the following trends can be ascertained: the first part contains most of today's theories and concepts in music therapy throughout the world, starting from ancient times and presenting, in its third chapter, the "Development of present Trends of Music Therapy in America" (Illing and Benedict). The second part deals with the physiopathological aspects of music's impact on the human being. Brain waves, psychosomatics, and electromyographic methods and their interaction with music are explored (Destunis, Deebandt, Stokvis (the editor of *Acta Psychotherapeutica*) and Traenkle). The third part is the largest and primarily devoted to therapy. Dreikurs (Chicago) describes music therapy with psychotic children, Martha and F. Bruner-Orne in Massachusetts illustrate the application of "English hand-bells in a psychiatric clinic," the editor of this anthology presents a valuable contribution of music therapy in private neuropsychiatric practice (with a wealth of scholarly research), and Wendt of the Karl Marx-University in Leipzig compares music and sleep therapy. In its fourth part, the book presents contributions by Dr. P. J. Moses of San Francisco investigating "musical elements in the voice of neurotics," and the editor's wife, Dr. H. Teirich-Leube, speaking of "Rhythm in the Gymnastics in Therapy." Since at least half a dozen of the contributors are American psychiatrists and psychologists, and since the frame of reference is extremely broad and often new and stimulating, the book appears to be most valuable and, hence, most welcome.

HANS A. ILLING, PH.D.,
Beverly Hills, Calif.

IN MEMORIAM

HANS W. GRUHLE

1880-1958

With the death of H. W. Gruhle in October 1958 at the age of 78, German psychiatry has lost one of the most independent and stimulating workers, a very successful teacher of the highest academic standing and a productive and critical writer in many fields of psychiatry. To understand his work and its far-reaching influence a few data of his life are of interest : He started his career as a psychiatrist under Kraepelin in Munich in 1904, but soon went to Kraepelin's earlier Clinic in Heidelberg where he spent the most fruitful years of his life. In 1933 he was removed from his academic position by the Nazis together with the holder of the chair and all other teachers at the Psychiatric University Clinic. For over 12 years he was in academic exile being in charge of 2 small mental hospitals in the country ; but he returned after the downfall of the Nazi regime in 1947 to the chair at Bonn University which he held till his retirement.

Like his teacher Kraepelin, Gruhle was convinced of the importance of *psychology as a basic science* of psychiatry ; but he freed himself early from the dependence on Wundt's association psychology. In a number of detailed studies on psychiatric symptomatology he applied ideas of contemporary psychologists such as Külpe, Stumpf, Müller and Bühler in psychopathological problems. In 1922 he wrote a small tract *Psychologie des Abnormen* in which he developed his own concepts in this field. His approach was and has remained phenomenological and descriptive ; but his refined and discriminative analysis e.g. of schizophrenic symptoms, has remained unsurpassed. The most original contributions to the problem of delusions ("Wahn") of this century are probably those of Gruhle. His attitude towards the various psychological schools can, perhaps, best be seen from the fact that he joined as co-editor the journal *Psychologische Forschung* mainly devoted

to "Gestalt"—psychology, but nevertheless remained towards this school as to all others also, the critical and independent worker on his own. For a number of years he held a lectureship in psychology, besides being associated professor of psychiatry, at Heidelberg University instructing teachers and educationists, but also had honour students in psychology.

The second branch of psychiatry in which Gruhle can be considered a pioneer was that of its *social aspects* and its relation to criminal and asocial behaviour. As early as 1911 he described the social implications of mental disease and pleaded for the need of special care for the family of the patient in hospital, at the time when Adolf Meyer conceived his idea of the psychiatric social worker. Gruhle's investigations of young offenders in an institution (1912) created the pattern for a sequence of similar studies of border problems between criminology and psychiatry. With the Heidelberg colleagues he founded and published a sequence of typical life histories of criminals ("Verbrechertypen"). Up to his death he was busy with a new edition of a famous text on forensic psychiatry.

Under Franz Nissl, at the time professor of psychiatry, a group of eminent young psychiatrists, among whom Gruhle played an important rôle, gathered at the Heidelberg Clinic before the first World War : they were Wilmanns, Homburger, Kronfeld, Jaspers, Wetzell, all from Kraepelin's school, and a number of younger workers who joined this circle later and were not less influenced by Gruhle's critical enthusiasm. In fact, his sharp and cool criticism was one of the most valuable assets of psychiatry in Heidelberg, and elsewhere. Jaspers once called him the living conscience of German psychiatry. He was a fearless fighter for what he considered scientifically honest and truthful and took

counterblows in debates and controversies with admirable charm and ease, without personal rancour.

His *chef d'oeuvre*, written during his exile from academic life, *Verstehende Psychologie* (Psychology of Understanding) (1948) represents an attempt at establishing psychology and psychopathology by methods outside the natural sciences—and to develop these methods in applying them in the psychology of language, style, handwriting, works of art, history, law and of

living itself. Its broad concepts and comprehensive insights will probably be a fruitful influence in discussions on the principles of psychological science for generations to come. A collection of Gruhle's shorter writings was published by himself in 1953 (*Verstehen und Einfühlen*) giving a clear picture of his lucid style and his mode of thinking. They would certainly deserve of an English translation.

W. Mayer-Gross, M.D.

SOURCES OF UNCERTAINTY IN STUDIES OF DRUGS AFFECTING MOOD, MENTATION OR ACTIVITY

ERWIN L. LINN, Ph.D.¹

INTRODUCTION

It has been difficult to specify the effects of many drugs. A review of the literature shows that this is particularly true of those drugs intended to change mood, mentation or activity. The central concern of this paper is to indicate some of the ways in which the characteristics of subjects and the social setting may obscure the determination of the effects of these kinds of drugs. Other questions of study-design—e.g. sample size, techniques of biological assay, and timing of dosages—will not be discussed.²

DRUG-EFFECTS : DEFINITIONS

Primary or intended effects.—A drug may have numerous effects but it is usually studied or administered for a particular effect expected. For example, reserpine "calms" hyperactive mental patients; it also lowers the blood pressure of hypertensive medical patients. Opiates reduce the pain of terminal cancer patients but also alleviate the withdrawal sickness of addicts.

Side-effects.—Side-effects are all effects other than the intended or primary effects. It is obvious that if the primary use of a given drug varies, so do the side-effects. What is side-effect to one intended use may be primary effect to another. For example, lowered blood pressure is a *side-effect* when reserpine is given with the expected effect of calming a mental patient but a *primary effect* when the same drug is prescribed for a patient with hypertension.

Side-effects are dependent on (a) the dosage and (b) whether treatment is single or continuous. It seems very difficult to limit drug-effects to one organ or area,

particularly as dosage is increased. When high dosages of chlorpromazine are used side-effects are not only wider in range but more serious(8, 9³); with continued use, most side-effects have been reported to disappear.

PROBLEMS OF INFERENCE FROM DATA ABOUT DRUG-EFFECTS

If the intended use of a drug is to change mood or mentation, the major source of information on its effects may be the subject's report of what he experienced. Even if the drug seems to achieve an easily and objectively recognized main effect, the observer, in arriving at knowledge about how a drug works, often depends on the subject's ability to understand and to verbalize his reactions. Moreover, while observable changes may provide a valid index of drug-effects, investigators may err in inferring subjective changes corresponding to these external signs(22). For example, agitated depressed patients who seemed calmed by chlorpromazine may still be contemplating suicide(1).

Thus, the subject's interpretation may be of considerable importance to defining and understanding specific drug-effects. If so, it behooves us to consider some of the influences upon what the subject perceives and reports.

First, of course, the subject's interpretation of drug-effects varies according to his "morbid state." The opiates have one meaning to the addict but another to the terminal cancer patient in extreme pain.

Experiences with *other* drugs, with which a drug new to the subject's experience can be compared, will color his reactions and what he tends to tell the investigator. For instance, among mental patients, it has been noted(11) that addicts given mescaline, unknown to them, report its effects as similar to opiate drugs, whereas alcoholics compared it to a "hangover."

The *continuing* experience with the same

¹ Laboratory of Socio-environmental Studies, National Institute of Mental Health, U. S. Department of Health, Education, and Welfare, Bethesda 14, Md.

² The writer is grateful to Dr. J. Cochin and Angelica S. Goffman for their critical comments about this paper.

drug may alter the subject's reaction and interpretation of drug-effect. Only to the extent that he learns what to expect, can he arrive at some set evaluation(10):

The mescaline stress produces much less reaction with succeeding experiences. We felt in the past that this might be due to such vague factors as "tolerance" or absence of any specific emotion-laden material. However, the first mescaline experience becomes a point of reference. It has been integrated as an experience and can serve as a basis for future exposures to the same stress without producing the emotion-laden discharge of the first time.

It has been argued that continued voluntary use of marihuana and addiction to opiates depend on the predictability of certain effects(3, 24). Moreover, knowing the range of possible effects through experience may lead to "psychological tolerance" of side-effects, especially when the subject greatly desires a major effect. For instance, the drug addict may find side-effects such as itching and vomiting pleasurable accompaniments to morphine injection(38).

The personality characteristics of subjects may necessitate a qualified interpretation of observed or reported effects(37). For example, some investigators have questioned the "normality" of the volunteer subject(20). One investigator has interpreted negative results with reserpine and chlorpromazine as due to an underlying "passivity" in the mental patients so reacting(33). A corollary to this idea of personality structure affecting drug-reaction is the hypothesis that addicts tend to select the drug of addiction (*e.g.*, alcohol, opiates) according to their personality needs(39).

Something which has been more systematically studied is the "placebo reaction" (21, 36). Moreover, some subjects have been demonstrated to be "placebo-reactors" or "placebo non-reactors," that is, reacting or not reacting to continued as well as to initial placebo because (it is assumed) of some underlying personality characteristics. In one study of drugs to relieve headaches, the placebo-reactors were inferred to have a different kind of headache than the non-reactors(18) :

If subjects never report relief through a pharmacologically inactive substance but always

report at least some attacks relieved through bona fide analgesics, it must be assumed that they represent a "pure culture" of physiological headaches not accessible to suggestion, while the . . . subjects who either always or most of the time responded to placebo represent, perhaps predominately, psychogenic headaches and to some extent also milder physiological headaches coupled with a tendency toward suggestibility.

Social background may also influence reactions to drugs or placebos, though we have found no such reference in the literature. Differences by ethno-cultural background in the manner in which pain is expressed by neurological patients and its meaning to them have been reported(41). We would expect, therefore, that ethno-cultural difference may be important at least to differences in pain relief from analgesics. Also, since hospitalized mental patients are disproportionately drawn from the lower socio-economic level of the population(7), such subjects' limited education may of itself interfere with their understanding of their reactions to drugs or with what the investigator would consider satisfactory reporting of such reactions.

It can never be taken for granted that the subject's perception and reporting reflect a direct pharmacological action of drugs which are intended to change mood, mentation or activity. For example, there is some evidence that the opiates reduce anxiety about pain(4, 5) as well as increase the pain threshold. Mescaline, lysergic acid and pervitin, in bringing about alterations in perception and body sensation, which seem to be physiological actions, may lead to anxiety, uncertainty, and, at times, rage, which may be psychological reactions not directly resulting from the physiological action of the drugs(17). Similarly, some of the side-effects of chlorpromazine and reserpine may have special meanings to mental patients with certain symptomatology, leading to anxiety and tension(27, 33, 40).

For drugs such as mescaline or lysergic acid, the jarring of the normal or the usual is the very thing the investigator wants to learn about, but this effect may hamper the subject's ability to perceive or understand his reactions and to communicate. Such

difficulties have been aptly summarized (34) as :

(1) Blockage—the absence of associations ; (2) "Subvocal flight of ideas"—too many associations occurring at once ; (3) "Mental ataxia"—the subject tries to communicate but there is a discrepancy between what he says and what he means to say ; (4) Expressive introversion—the subject becomes so pre-occupied with his images and hallucinations that he neglects to communicate at all ; alternatively he may *think* he has done so when in fact he has said nothing ; (5) "Mystical thinking"—vague statements about "Time," "Reality," "Truth," etc.

On the positive side of the ledger, probably more will be learned about the tranquilizing drugs than about electro-convulsive or chemically-induced convulsive therapies because patients can describe the improvement that takes place during chlorpromazine or reserpine treatment, whereas the former therapies impaired the memory (26).

Finally, the social setting of the treatment may become important to the subject's interpretation of drug-effects. Since the social setting has wider ramifications to the determination of drug-effects than just influencing the subject's interpretation, it will be discussed more fully below.

THE SOCIAL SETTING

All research and therapy with drugs take place in some social setting. The extent of social participation is influenced by whether treatment is with a private physician or under institutional auspices, the kind of subject, and the continuity in time of the therapy or research. Mutual participation of subjects and staff varies from outpatients, in occasional contact with staff and just waiting room contact with each other, to mental patients, confined in a constant potential of contact with fellow patients and attendants.

Normal subjects, former drug-addicts or mental patients are often brought together for the experimental use of drugs intending to change mood, mentation or activity. What this grouping means to the subject must be seen in contrast to the world from which he has come. The mental patient may be most affected by the transfer to an

environment devoted to treatment and research rather than to custody (13). For example, in one study, 39 out of 48 patients brought to a ward for drug treatment showed improvement prior to the inception of drug treatment (31). Another writer (2) has claimed that

any attempt to observe a form of behavior in our patients has often led to a change in that form of behavior. We have found it to be most marked with regard to aggressive behavior and its immediate consequences but it has also applied to other forms of behavior. We have several times seen patients hide the evidence of their incontinence when an experiment was in progress who had never been known to do so before.

When subjects are brought together but introduced to the therapy at staggered times (19), knowledge about drug-effects may be gained from those already in treatment. In research at the National Institutes of Health we found that normal volunteers developed a ward "folk lore" about drugs they were given and tended to label unknown drugs, as, for example, "the stuffy-nosed one" (which turned out to be chlorpromazine). Similarly, comments of patients recorded in the nursing notes of a mental hospital indicate that insulin and electroshock had their "reputations" among mental patients as do the current crop of tranquilizing drugs.

The dramatic effect that certain drugs have can intensify the communication about them. The orthostatic hypotension caused by chlorpromazine, the hallucinations caused by LSD, the gaiety caused by dexedrine : these create experiences which particularly for normal subjects are sharply distinct from the usual behavior patterns of their group.

Probably more influential than verbal exchange is what is witnessed directly. An extreme side-effect such as jaundice may be a statistic of one out of a large number of patients treated with chlorpromazine but the number of others apprehensive because they witnessed this side-effect is not limited to one.

Equally important may be staff day-to-day experiences with the drug. With chlorpromazine or reserpine, the initial trials in particular may alarm the mental hospital

staff if cases of dermatitis, jaundice, and Parkinsonism occur, and this alarm may be communicated to patients. In one study, is a specific part of the research design, the staff was reassured about side-effects (35). Eventually, the staff gains a sense of ease about the drug as they learn the range of effects and some means of handling unpleasant side-effects.

When subjects who have been brought together are treated with the same drug, there is the possibility of a heightened effect due to their having a similar reaction at the same time. We are all familiar with how the "mood" of the group may be heightened by the effect of a specific drug, alcohol, and how then, in turn, the alcoholic effect may be re-inforced by the "mood" of the group. What happens when one subject receives a drug with an *opposite* effect from that of other drugs administered to other subjects is being investigated (30):

Cooled up with, say the egotistical benzedrine partner, the withdrawn, indifferent dramamine partner and the slightly bored lactose man, the second subject reports that he is distractible, dizzy, drifting, glum, defiant. . . . This is not the report of mood that we got when all four men were on secondal.

Then there is the question of what is considered "proper" social behavior in a group of subjects. Drug reactions which make the subject feel irritated with others may be suppressed or not admitted, whereas being pleasantly disposed or "high" may be expressed without stepping too far away from social controls. Normal volunteer subjects observed by the writer were reluctant to admit that they became irritated by a drug, eventually identified as chlorpromazine. They did talk about such feelings, if asked, and two or three wrote up detailed descriptions about how they tried not to express such feelings.

Standards of behavior may also be pertinent to what kinds of behavior become contagious. If some mental patients are given drugs and as a result behave in an "improved" manner, the more accepted behavior may be taken over by others (23). These types of changes are possibly similar in kind to those, already mentioned, noted to occur even prior to treatment when patients are brought to a ward preparatory

to the experimental use of drugs. The contagion of desirable behavior has also been noted in another context (15). Incontinent patients brought together with continent patients for occupational therapy gradually decreased their incontinent behavior until it "no longer constituted a problem during the daily hour in the clinic. It recurred, however, when the patients returned to their wards." A central problem is why desirable behavior becomes contagious if drugs are effective and why the undesirable behavior is not an effective counter-influence to the drug action. Perhaps this is a matter of shared values (the socially desirable behavior being shared), or is a matter of numbers (the successfully drug treated group being larger). The problem of social contagion of desirable behavior is further complicated because its opposite is known to occur—e.g., *folie à deux*, mob behavior, dancing manias (16).

Perhaps it is not so much that drug-induced behavior is socially contagious as that it produces a different environment for all patients, including those not receiving the drug. For instance, if chlorpromazine or reserpine reduces the hyperactivity of some patients, it thereby reduces the provocative incidents to which other patients are exposed (6, 12, 35, 40).

If patients improve, staff attitudes towards patients change, and staff has more time for activities other than controlling patients. These changes in staff attitudes and activities will affect the subsequent behavior of all patients, whether they are treated or not (25, 29). Even existing staff attitudes about a drug prior to its use can prove a sharply distinguishing predictor of whether or not patients improve when treated (14).

Finally, for confined patients, a distinction must be made between symptoms that are psychiatric—i.e. reflect pre-admission etiological dispositions and represent a continuing personality malfunctioning—and symptoms that are due to adjustments and reactions to being institutionalized. For example, chronic mental patients have exhibited sexual reactions under the influence of mescaline. These were interpreted in psychiatrically dynamic terms (11). However, it is equally plausible that the sexual

reactions to mescaline resulted from the restriction on sexual life inherent in the confines of the mental hospital.

RELEVANCE OF THESE OBSCURING CIRCUMSTANCES TO STUDY-DESIGNS

Though the foregoing is not a complete catalogue, we can conclude that drugs used to change mood, mentation or activity are given under many conditions which obscure the determination of drug-effects. These have been arbitrarily divided to permit ease in our discussion, not because they can be usually isolated in therapy or research. The question now arises: What can be done in drug research to control or eliminate these obscurities?

Anyone who has seen subjects given a high dosage of drug is well aware that drug-effects seem to be the only important thing occurring and that the setting or the type of patient exerts no or little influence. With lesser dosages, these other factors seem more important. However, the pattern of importance varies. For example, the mood of the group, if it is similar to the mood created by the drug, may obscure the drug-effect. If the subjects are chronic mental patients, the apparent poverty of patient interaction may lead us to question the importance of group influence.

Nevertheless, one must watch what one is taking for granted. For example, we know that high dosages may engulf the potential influences of some of the obscuring circumstances discussed. However, it is usual, at least in treating mental patients with the tranquilizing drugs, to begin with low dosages, which are gradually increased. During the initial period of drug treatment, at least, dosage may be secondary to the treatment setting as a determinant of changes in patients. Chronic mental patients may not speak much to each other but the reports about changes in such patients when brought to a ward for treatment, even prior to the treatment, and about the effect on untreated patients of social contagion, decreasing provocative behavior, and staff attitudes would indicate that lack of social interaction cannot be taken for granted.

Double-blind procedures with control and experimental groups are clearly neces-

sary if definitive, unbiased results of what a drug does is to be obtained(32). Since there are perhaps more obscuring circumstances than can be recognized or eliminated, it is only reasonable to attempt to have the control, untreated group exposed as similarly as possible to the same circumstances as the treated group(35).

It is not reasonable to claim, as has been done, that placebos are silly because side-effects can be recognized. This certainly is not always true. There are placebo responses and these could be taken to be the effects of the true drug. The effects, main or side, from the drug itself are usually not found in all patients and some have no reaction at all. There is the additional problem of placebo-reactors but these could be eventually identified and analyzed separately.

During continued use and higher dosages, drug-effects may become pronounced enough for recognition of the drug-treated patients. Yet, the controlled study under these circumstances is still more valid in its results than the judgments from clinical trials in which all subjects are given the drug to be tested. Knowledge about drug-effects is not spread equally among the persons concerned, especially in initial trials of a new drug. Doctors, through already published material and their prepossession with clinical or research experiences, may know of cues that distinguish the drug under study. Least in knowledge about such cues would be the subjects themselves, if we may exclude from this discussion the sophisticated drug-addict. Therefore, even a double-blind study may not eliminate the bias of staff knowledge about drugs, but it still may eliminate the bias of the subjects' knowing whether they are receiving drug or placebo. Perhaps no better argument can be made than that expressed after a 73 day double-blind study of reserpine(28):

... at the conclusion of the experiment, no one was able to assess better than by chance who was given the drug. . . . The importance of the double-blind structure was additionally illustrated by what happened to the ratings of patients once their identity became known. Thirty days after the end of the study proper, patient identity having been divulged to, the

raters, 100% of the experimental group was rated as significantly improved on one of the scales.

If drug induced behavior affects the non-treated through social contagion or through changing the environment the differences between treated and non-treated patients will consequently be diminished. This could veil an appreciable effect of a drug. Some of the problems of setting can be eliminated by having experimental and control subjects scattered over many wards so as to diminish the potential influences of witnessing or communicating about drug-effects, or of benefiting socially from improvements in other patients.

Sometimes the attempts to regulate interfering variables have further complicated the possibility of evaluating the drug. For instance, with the tranquilizing drugs, there are many reports of the clinician making day-to-day judgments during the study about toxic effects and or patient improvement and thereby varying the day-to-day dosages. Yet, if the purpose of the study is to evaluate the tranquilizer, this varying of dosages for each patient means incorporating into the process of study criteria of side-effects and or main effect that are to be used eventually to gauge the drug. Thus, the study comes not only to be an evaluation of the drug's effectiveness but also an evaluation of the clinician's judgments during the study. It is furthermore complicated by each patient having a different series of treatment.

SUMMARY

Research on the effect of drugs, particularly those affecting mood, mentation, and activity, is complicated by a number of obscuring factors. Many of these complications seem inevitable in terms of the nature of the drugs or the available subjects. Until some of these complicating factors can be documented as inconsequential, investigators must try to randomize their potential effects or to take explicit account of them in the research design.

DIFFICULTIES OF COMPARATIVE PSYCHIATRY : THE FIJI ISLANDS¹

ERIC BERNE, M.D.²

This discussion is intended to illustrate the serious difficulties which arise, even under favorable conditions, in making studies in the field of comparative psychiatry (sometimes called social, ethnic, or cultural psychiatry). Because such studies are becoming increasingly influential not only in psychiatry, but also in psychological, sociological, and economic circles, it is desirable for comparative psychiatrists to be especially rigorous in considering their findings, and to avoid making unwarranted or gratuitous interpretations.³

The Fiji Islands are a particularly favorable area for the study of comparative psychiatric epidemiology because of the completeness and reliability of the archives and because psychiatric censuses of the whole population were taken in 1911, 1921, 1936, and 1946. They offer the additional demographic advantage that the present population of 333,000 (1954) is almost equally divided between two inbred groups of different racial and cultural backgrounds. This population consists of 42.9% Fijians and 45.1% East Indians, the other 9.0% being made up of Europeans, part-Europeans, Chinese, and other Pacific races (1).

An epidemiological ideal would postulate the determination of the "true prevalence" of a given condition. This would require (a) definitive diagnostic criteria, (b) the testing of every individual in the population, (c) by competent technicians, (d) at the same instant. In the Fiji Islands this has been approximated in the filariasis survey by the clinical and hematological examination of almost 50% of the Fijian population of 143,100 (1954) over a 10

year period. In this case requirements (a) and (c) have been categorically met while (b) and (d) require statistical correction.

In the case of psychiatric illnesses, however, difficulties arise in all 4 respects. There are no pathognomonic criteria, and the classical position that they can be defined relative to the local culture is open to question (2). Even in highly sophisticated communities, medico-legal opinions show that radical differences of viewpoint may occur. The second requirement of comprehensiveness has been met in several places in the South Pacific, officially in Fiji by the census-taker and unofficially elsewhere. The third requirement of obtaining enough qualified diagnosticians is almost insurmountable in dealing with any sizeable population, even one as small as the 8,700 Hutterites studied by Eaton and Weil (3). So far there is no report in the psychiatric literature in which requirement (d), simultaneity, has been met.

The deficiencies of informal screening are demonstrated in two neighboring islands in the South Pacific, each with an equally well-qualified, British-trained medical officer, who in effect took periodic "complete medical censuses" of their populations through their staffs of visiting nurses and through personal tours. One M. O. stated that except for a few senile dementis his island was free of gross psychopathology, while the other said that he was sure that on his island there were many psychotics in the villages whose condition was concealed from the authorities. The first M. O. had been sent out from England, the second was a native-born white with an intimate acquaintance of his fellow-citizens.

PREVALENCE

With these qualifications in mind, the census figures for the Fiji Islands may be considered. In the 1946 census, the question relating to psychiatric problems was similar to that asked in previous years, and read as follows :

¹ Read at the 114th annual meeting of The American Psychiatric Association, San Francisco, Calif., May 12-16, 1958.

² P.O. Box 2111, Carmel, Calif.

³ Thanks are due to Dr. H. W. Conran, to Dr. Lindsay Vertier, demographer in the Medical Department of the Colony of Fiji, and to Miss Dorothy Crozier, Government Archivist for the Colony, for their time, effort, and guidance, as well as to other members of the Medical Department who assisted me in various ways.

State the name of any person in this dwelling or establishment who is (a) Totally blind, (b) Nearly blind, (c) Dumb, (d) Lunatic, imbecile, or feeble-minded.

This question was printed on the census form in English, Hindustani, and Fijian. The following is a summary of the available figures for the censuses of 1911, 1921, 1936, and 1946. There is a breakdown for 1911, but none for the later years. The first 3 columns give the actual figures, the last 3 the rate per thousand.

	1911(4)					
	Total	Indians	Fijians	Total	Percentage Indian	Fijian
	27	11	8	0.2	0.3	0.1
Lunatic						
Imb. &						
Feeble	216	71	131	1.5	1.7	1.5
Total	243	82	139	1.7	2.0	1.6
	1921(5)					
Total	162	103	39	1.0	1.7	0.5
	1936(6)					
Total	176	130	33	0.9	1.5	0.3
	1946(7)					
Total	298	196	90	1.2	1.6	0.6

In epidemiological terminology, these figures constitute *prevalence ratios*, which measure the proportion of the population which exhibits a phenomenon at a particular time(8). Since every individual in the population was "tested" almost simultaneously, they approach the ideal in regard to criteria (b) and (d), comprehensiveness and simultaneity. But there are serious conjoint defects in regard to criteria (a) and (c), diagnosis and competence. The criteria are not stated and the "technicians" were lay census-takers and the families of the afflicted. The distinction among English speakers between "lunatic" and "imbecile" must take on a retroactively increasing vagueness in the various census years, and the exact connotations in each village of the Fijian equivalents ("lialia" and "yalolevu") can never be known. Nevertheless, with all their defects, the Fijian census figures are probably the best available for any non-Caucasian indigenous population.

Disregarding the distinction between "lunatics," "imbeciles," and the "feeble-minded," since accurate diagnosis is too much to expect from village people, the sense of the figures is that the prevalence of psychiatric disorders in the Fiji Islands

fell between 1911 and 1921, and remained fairly constant for the next 25 years.

These tendencies are significant because they run counter to popular beliefs about the etiology of psychiatric disorders. If this array is accepted at face value, such disorders were more prevalent in the horse-and-buggy, pre-industrial, pre-tourist, pre-World War I days than they have been in the later era of automobiles, industry, "cultural contamination," World Wars, and changes in the economic system. The constancy of the prevalence ratio in the last 4 censuses is just as impressive in this respect as the initial fall, and may also indicate a certain reliability in the figures. There is no indication that in this "island paradise" "things were better in the old days," when it was actually, from an American and European point of view, more of a paradise in many ways.

Comparing the two major segments of the population, there is relatively little variation in the figures for East Indians, with a greater fall in the prevalence ratio among Fijians. Yet it was the Fijians who experienced the greater cultural, social, and economic changes as the decades went by(9), all in the direction usually considered by sociologists and anthropologists, as well as by the laity, as "harmful." The most obvious change was in the direction of relinquishing instinctual freedom, because cannibalism, widow murder, and certain sexual customs were forbidden(10). Up to the time of the cession of the Islands to Great Britain in 1874, the indigenes were said to be literally eating each other up, so that in 1946 cannibalism was still a family matter, in the sense that a percentage of the very old had either partaken of it, or personally observed it, or had had relatives eaten; and among the younger groups, a proportion had had parents or grandparents with a similar personal experience of cannibalism. A parallel may be drawn with the institution of slavery in the United States, whose relics still influence social behavior and seem to offer a screen for psychopathological acting out in some cases.

The census figures indicate that counter to current expectations, the so-called "stress of modern life" and all that it implies has

had either no effect on the total prevalence of psychiatric disorders in the Fiji Islands, or an effect opposite to the anticipated one.

INCIDENCE

The incidence rate is defined by epidemiologists(8) as the number of events in the population at risk during a specified time, compared to the mean population at risk during that time. A "true incidence" rate would require (a) that every possible case be accurately diagnosed, and (b) that the time of onset of each case be accurately determined. In the case of psychiatric disorders, it is unlikely that these criteria will ever be met except in regard to certain toxic conditions. In general, the difficulties of diagnosis are complicated not only by such factors as the psychosomatic and sociopathic problems, but by the problem of the "cut-off point," when to call something an idiosyncrasy, and when to call it a disorder. As for the "time of onset," in most cases this can only be stated in a superficial sense which few clinicians would accept; this is an impractical requirement for any population beyond the number undergoing intensive psychotherapeutic study and those suffering from toxic psychoses.

The only practical compromise is to ascertain how many cases are brought to the attention of competent diagnostic authorities during a specified period. In practise, this means totaling first admissions to hospitals and clinics, and also, if sociopaths are included, first offence convictions for significant crimes.

Unfortunately this system gives an approximation so rough as to be almost without value for epidemiological purposes, since it appears that first admissions to clinics and hospitals in a given locality do not indicate either prevalence or incidence, but rather the quality and quantity of the facilities available and the local attitude toward psychiatric treatment. The tendency is to fill good facilities as rapidly as they are provided and public opinion permits(2). The only instances known to the writer where public facilities regularly have vacancies is where those facilities are markedly below standard, as in Haiti, or formerly, in French West Africa. In applying the formula for incidence rates to

hospital figures, it would be more satisfactory to take the "event" observed at face value. This event is the admission of a patient to a hospital, and the usual "incidence rates," accurately interpreted, reflect only the tendency of mentally ill people to arrive at a hospital and not the prevalence or incidence of mental illness. In the Fiji Islands, because of the small numbers involved (ranging from 15 in 1911 to 61 in 1954), the admission roster of the Government Mental Hospital, taken by itself, is of little value.

RACIAL DIFFERENCES

A more vigorous approach, open to methodological criticism but useful in practice in view of the difficulties encountered with other approaches, is an attempt to answer the question: "What proportion of each of the two predominant races exhibited gross psychopathology during a given year?" These ratios will be denoted by the symbol PSYR.

The crudest index of PSYR is the mental hospital population, which may be denoted MHP. This consisted of 43 Fijians and 125 Indians during 1954(11), yielding rates (MHPR) of 0.30 and 0.78 per 1,000, respectively; a ratio of 1:2.6. It is well-known, however, that Fijians are reluctant to seek hospital care(12). This can be illustrated quantitatively as follows. In 1954, the crude death rate for Fijians was 11.00 and for Indians 8.60(11). During the same year about 3,900 Fijians and 6,300 Indians were admitted to general hospitals, giving general hospital admission rates (GHAR) of 27.2/1,000 and 39.2/1,000 respectively. Taking the crude death rate as an index of actual need for hospitalization (NHI), then the Indian NHI was only 0.78 of the Fijian NHI (8.6/11). But the Indian GHAR was 1.44 times the Fijian GHAR (39.2/27.2). This indicates that Indians are more apt than Fijians to seek hospitalization when needed. The index of this tendency to seek hospitalization when needed (TSHI) is given by GHAR/NHI, in this case 1.44/0.78; meaning that the Indian TSHI is 1.85 times that of the Fijian TSHI (39.2/8.6: 27.2/11.0).

Applying this TSHI ratio to the mental hospital population, the corrected MHPR

for Fijians is 0.56/1,000 (0.30×1.85), equivalent to adding 37 more Fijian patients; and the PSYR Fijians : Indians is only 1.39 ($0.78/0.56$) instead of 2.6.

If it is permissible to consider gross sociopathy in computing a more accurate PSYR, then certain criminal offences should be taken into account. In 1954 there were sentenced to imprisonment or whipping, 48 Fijians and 13 Indians for sex crimes, and 47 Fijians and 35 Indians for crimes against persons, ranging from manslaughter to simple assault (13). If these figures are added to the corrected figures for hospitalizable mental illnesses, totals are 175 for Fijians ($(43+37) + 48+47$) and 173 for Indians ($125+13+35$), yielding practically equal PSYR of 1.2 and 1.1 per 1,000, respectively.

There is one more set of figures available. Admissions for psychiatric conditions (Internat. List of Causes of Death, 1929, A67 & A68) to general hospitals throughout the Islands (11) comprised 20 Fijians and 49 Indians. Adding these to the previous grand totals yields PSYR of 1.4 in each case. Correcting the last two figures for various possible discrepancies does not alter the situation. Therefore the best available estimate for the PSYR indicates equality in the exhibition of gross psychopathology by the two races during 1954.

This *tour de force* is intended to demonstrate that as more and more figures of likely significance are considered, and indicated corrections are made, the less probable it appears that there are racial differences in the frequency of occurrence of major psychopathology in this large population. This indicates that whatever their differences in cultural and social dynamics, and in their exposure to the "stresses of modern life," the two races are equally subject to such disturbances. In my opinion, based on the experiences of other colonial populations, if increased and improved treatment facilities were provided for the Fiji Islands, and time allowed for the education of the public, the mental hospital population would approach the maximum ratio represented by the United States. This development has already been approximated in the much more primitive district of French Guiana, is under way in

Trinidad (2), and is anticipated in planning for the Philippines (14).

DISCUSSION

The assumption that there were indigenous populations who existed somewhere in recent times, free of "modern stress" and "social disorganization," and consequently with little or no mental illness, requires more careful study. The history of most islands or enclaves which supposedly once met these criteria is really one of repeated waves of invasion and warfare, with recurring impositions of new stresses, important cultural changes, and new social organizations. If comparative psychiatry is to be a scientific discipline, then certain criteria will have to be approximated, certain difficulties faced, and more rigorous criticism of data and their interpretation exercised. If reasonably reliable figures concerning the grossest kind of psychopathology are subject to the kind of review which has just been demonstrated, this must apply *a fortiori* to studies of more subtle variables.

1. Prevalence and incidence should be more clearly distinguished (3), and both should be distinguished from MHPR (15). By analogy, the number of conceptions in a population cannot be determined by using an uncorrected birth-rate: and the number of babies born in hospitals at various epochs does not indicate either the prevalence of pregnancy or the incidence of conception.

2. Epidemiological data in psychiatry should be gathered, sorted, and interpreted by clinical specialists rather than by workers from other fields of medicine or the social sciences. The actual processing of data, however, is usually more effectively carried out by social scientists than by clinicians.

3. Generalizations should be based on adequate data. The fact, for example, that there is a heavy incidence of toxic psychoses in French West Africa, Southeast Asia, the Caribbean, and French Guiana (2) is a temptation to generalize this observation to include all tropical areas. But in the Fiji Islands, toxic psychoses are less prominent. Thus if a phenomenon is claimed to be general, it must be based on

observations which are literally world-wide.

4. The present crisis is a bias toward the "cultural" viewpoint at the expense of genetic and other aspects. This has some of the aspects of a romantic movement rather than of an adequately documented theoretical shift. The "cultural" literature often contains methodological flaws, leading to the dissemination of inadequately supported or unwarranted conclusions, with little or no mention of dissident opinions. Many of the phenomena nowadays popularly attributed to cultural influences might equally well be attributed to genetic, constitutional, somatotypic, traumatic, or other factors, and these possibilities must be more rigorously excluded if the cultural school is to be taken seriously.

5. In any case, the cultural approach should be re-examined because personal contact with people in different parts of the world hardly supports it. The differences between individuals in any culture seem to be greater than the differences between "cultures." Clinically, cultural differences can be effectively treated as mere dialects or accents of a common language: the Italian schizophrenic speaks schizophrenic with an Italian accent, and the Siamese manic speaks manic with a Siamese accent. The chronic female closed ward can be located from earshot on any continent. The interchangeability of clinicians is the most compelling single fact in comparative psychiatry: the migratory psychoanalyst, the transferred French colonial Medical Officer, the psychotherapeutic approach which is as effective in the Fiji Islands as it is in Trinidad.

SUMMARY

1. The complete psychiatric census of the Fiji Islands which has been taken periodically since 1911 meets some of the requirements for determination of the "true prevalence" of psychiatric disorders. It appears that such disorders were more frequent in the pre-industrial, pre-war era than in the later era of so-called "modern stress." The Fijian segment of the population experienced more change of social structure than the Indian segment, while the prevalence of psychiatric disorders ap-

parently decreased among the former. Both these tendencies run counter to current popular beliefs.

2. Hospital admission rates are of little value in determining the incidence of psychiatric disorders, since they represent the tendency to seek hospitalization, rather than the need for hospitalization. This difficulty can be approached by the use of other appropriate information to devise a correction factor.

3. An apparent cultural or racial difference in the quantitative exhibition of psychopathology, by Fijians and Indians respectively, becomes less and less as more information is considered, until it can be shown with some likelihood that the actual rates are equal. It is not improbable that the actual rates are approximately equal all over the world.

4. Certain requirements for a scientific approach to comparative psychiatry are outlined, principally the use of more rigorous epidemiological methods, and the attenuation of the current bias toward "cultural" etiology with its obfuscation of other important possibilities.

ADDENDUM

Since this was written, the writer has made another visit to the Fiji Islands to check his findings. The two most experienced authorities in the matter, Dr. Lindsay Verrier, Demographer of the Medical Department at Suva, who has a genealogical and medical file on every Fijian in the Islands, and Mr. C. C. Sachs, Chief Attendant at the Government Mental Hospital in Suva, who was born in Fiji and knows the Islands intimately, both agree that the implications of the figures given here are correct; in particular, that mentally disturbed Fijians are less likely to be hospitalized than mentally disturbed Indians, and that the present statistical findings need not be regarded as a *tour de force*, but probably fairly represent the actual situation.

SEVEN YEARS OF AWAKENING¹ 1906-13

EARL D. BOND, M.D.²

Two reasons impel me to write about the years 1906 to 1913 in American psychiatry.

The first is that the great beginnings which came in these years, while mentioned separately in every historical account, have not been brought together. Anyone at all interested in psychiatric history knows about the decade of the eighteen-forties and its advances in hospital building, treatment and spirit; the founding of the American Psychiatric Association and its Journal, the amazing achievements of Dorothea Dix. Then the headway made in this fabulous decade, marred by a natural impulse to claim too much (an impulse which still raises its well-meaning and over-optimistic head) was followed by over 50 years of doldrums: a time when inventive medical minds turned toward the wonderful histological and pathological advances in medicine and surgery. What is not emphasized is that this static half-century was ended, and another advancing half-century begun, by several new events and many adventurous men crowded into 7 remarkable years.

The second reason is that I bridge the gap from 1908 to 1958 and I saw the changes at first hand as an innocent bystander. In 1908 I was in charge of a men's psychiatric service and a men's training school of nurses at McLean Hospital near Boston, part of the Massachusetts General Hospital. My qualifications—as judged by 1958 standards—none. I knew personally, or came to know, most of the men who began one new thing after another and I was affected by all of the events as I saw conditions before and after. I hope that my recollections of the persons involved may make them seem less remote.

The long standing doldrums, then, were broken through by winds from nine directions. There was, of course, some over-

lapping of forces. There was also an historical preparation in scholarly articles by Clarence B. Farrar beginning in January, 1908 in the *American Journal of Insanity*.³ Dr. Farrar's title was "Some Origins in Psychiatry"—his nomenclature already in advance in that of the Journal of which he was to be Editor-in-Chief.

1. In 1906 a first psychiatric hospital for teaching and research purposes was opened at the University of Michigan, with Dr. Albert Barrett as Director and teacher of psychiatry to the Medical School. Well educated in neuropathology at the Universities of Harvard and Heidelberg, Barrett had been pathologist to the Danvers (Mass.) State Hospital. When he left, first Ernest Southard, then Herman Adler took his place at Danvers.

When the second teaching hospital, The Boston Psychopathic, was ready in 1912 both Southard and Adler were assigned to run it. Southard saw to it that the job as Pathologist at Danvers came to me and this position tied Barrett, Southard, Adler and myself in close friendship and professional interests.

A curious incident cemented the tie between Southard and myself at the dedication of the third teaching hospital, The Phipps Institute at Johns Hopkins, under Adolph Meyer. Southard was in the audience on that occasion in 1913, feeling very much hurt because Dr. Meyer had not seen fit to include Massachusetts psychiatry in his program. However, when Dr. Harvey Cushing, the principal speaker, announced unexpectedly that he had not known what to talk about until Dr. Bond from the Danvers State Hospital, had shown him interesting cases of pituitary disorders, Southard sat in chuckling, boyish glee. And so the Danvers State Hospital in important and unimportant ways entered into the beginnings of all 3 pace-setting hospitals.

2. It is appropriate here to mention the lectures and the articles in which Adolf

¹ Read at the 115th annual meeting of The American Psychiatric Association, Philadelphia, Pa., Apr. 27-May 1, 1959.

² The Inst. of the Pennsylvania Hosp., 111 North Forty-ninth St., Philadelphia 39, Pa.

³ Vol. 64: p. 523.

Meyer set forth in 1906 through 1910 his great new "Conceptions of Dementia Praecox" which broke down static ideas and considered psychosis as reaction⁴ to all that had happened in a patient's earlier life. He and his formulations (Psychobiology) are a part of American psychiatry.

When Meyer was President and I was Secretary of this Association we shared a suite of rooms and the chambermaid said that we were the cleanest men she had ever known. We neither smoked or chewed tobacco and we did not drink. I basked in the reputation until at a later annual meeting younger and rowdier friends of mine left my room in a mess and I departed with no compliments from anyone.

Working in these years in close touch with Meyer until his untimely death was August Hoch, whom I followed at McLean Hospital and who inspired my first 4 years of psychiatry. It was Hoch who focussed interest on *Personality and Psychosis* and brought into use the term Shut-In Personality.

3. In 1908 the classifications of Kraepelin were making themselves felt through condensations of his books in the United States and England. Here was order, scientific thinking, facts that could be demonstrated: here were pictures of the psychoses from the outside. Kraepelin's classification had been used in the Worcester State Hospital as early as 1896 but it took many years to infiltrate the minds of most psychiatrists. In 1907 and 1908 articles in the *Journal* still spoke of the *new* ideas and the *new* classification of Kraepelin. As late as 1916 Dr. Strecker, Dr. Orton and I received a letter from Kraepelin authorizing us to make a translation of his 3-volume psychiatry: we had finished the first volume when war stopped us.

4. In 1909 came the first real impact of Freud on the United States, his only visit to America. I was in Boston, in charge of a psychiatric service near Worcester and I could have seen and heard Freud if I had wanted to but I never made an effort. Here was a man from Vienna with strange

ideas—"a Prof Freund," the newspaper said. Then his ideas were about neuroses, which were rare conditions found in the offices and outpatient clinics of the neurologists and especially in Vienna and Paris. Neuroses were Un-American. But I was lucky in the aftermath of this visit to know Dr. James J. Putnam as teacher, therapist and quietly great human being. That Dr. Putnam, deeply religious, secure in academic and social position, professor of neurology at Harvard, 63 years of age, simply accepted many novel ideas of an insecure Mid-European, who behaved very neurotically, just because they were to him essentially true, is a landmark in psychiatry. The secure, undisturbed friendship between the two contrasting men was to Freud a life long joy. But it was years before analytic interest reached the psychoses and in the interval there were interminable debates in the Boston Society for Neurology and Psychiatry—as I look back on them they seem to have focussed on some person's totally erroneous notion of what psychoanalysis was: they never touched the real issues.

Later the fact that Dr. A. A. Brill, the translator, and Drs. White and Jelliffe, the explainers of Freud's position, were all well acquainted with the psychoses and personally known to me made it easier to read their books and gain an inkling of what Freud was really talking about. White's *Outlines of Psychiatry* and White and Jelliffe's remarkable *Nervous and Mental Disease Monographs* both came out in 1907 and gradually brought analytic terms into general use. And in 1913 Jelliffe brought out the first periodical in English devoted to the new ideas, *The Psycho-Analytic Review*.

5. In 1909 also came the first Child Guidance Clinic, established by William Healy in Chicago under the awkward name of Juvenile Psychopathic Institute: and Healy's classic *The Individual Delinquent* (1914). My personal ties with Healy were fixed by a week's walk with him and Walter Cannon before any of us had an M.D. We were accompanied by the essayist Samuel McCord Crothers and I like to think that all four of us developed an interest in the affairs of the mind. Mr. Crothers put psy-

⁴ Fundament Conception of D. P., *British M. J.*, 2: 1906; Nature and Conception of D. P., *J. Abn. Psychol.*, 5: 1909-1910.

chiatric thinking into delightful words in his essays—particularly his *Pardoner's Wallet*. Here is a sample. In the minds of all of us there is a "Forbidden City inhabited by a lawless crowd known as the Prejudices. Some are—dangerous fellows to meet in the dark." Others are "harmless folk, against whom the worst to be said is they have a knack of living without any visible means of support." William Healy, now 90, sent me a letter from Florida under date of March 11, 1958 in which he remembers—as too many others forget—the influence of the "ladies of Hull House" and the gifts of Mrs. W. F. Dummer that originated and put into action the "idea of studying the problems of children before doing anything about them." At present Healy himself is studying nuclear physics and keeping up with general world affairs.

6. In 1908 Clifford Beers and in 1912 Dr. Thomas Salmon began to focus the interest of public spirited citizens first on psychiatric hospitals and then on psychiatry in general. Beers wrote the classic, "*A Mind that Found Itself*," an excited but fundamentally true account of his mistreatment as a patient in private and state hospitals. Beers, aided by Dr. Adolf Meyer, encouraged by the great response to his book, went on to found Connecticut Mental Hygiene Society in 1908. In 1912 the formation of a National Committee for Mental Hygiene was made possible by Dr. Salmon's coming as Medical Director. The two men were a team: Salmon gave a sure professional leadership which balanced Beers' up-and-down enthusiasm. While I knew Beers, I was a close friend of Dr. Salmon's and helped to put the story of his life into book form. Undoubtedly for years he and Adolf Meyer were the leaders of American psychiatry—Salmon as a doer, Meyer as a thinker. And yet Salmon—and this says a lot about the disorganization of the psychiatric field in his time—had no preparation for psychiatry except his character. He had had 3 years of medical school, no college, no internship, no residency—he "just grew" after being assigned to study an epidemic in a State Mental Hospital—grew to become President of this Association and first professor of psychiatry at Columbia University.

The Mental Health Associations of 1959 are in direct line of succession to the 1908-12 events. Somewhat condescendingly someone wrote of Beers: "In elation he conceived a grandiose plan to form a world-wide movement." In other words Beers foresaw the present *World Federation for Mental Health*.

7. From 1909 to 1913 some discoveries about the bodily organs began to have effect on psychiatry. Cannon at the earlier date began to show to any doubting person the effects of emotion on the stomach, on adrenalin, on the body in general. He made it easier for the general practitioner and internist to accept some psychiatric ideas. Cannon was my closest friend as he went through Medical School and later he became co-grandfather of 4 of my grandchildren.

At the later date Moore and Noguchi discovered and confirmed the spirochete in human brains. I have had the experience of diagnosing (pretty well) and treating (pretty poorly) many paretics before this discovery. I quote from a textbook of 1907, "General paralysis is pre-eminently the disease of the brain-worker."

It seems to me that in line with these two findings have been the shock treatments and the double set of drug therapies—the penicillin-sulfa attacks on infection and the "tranquilizers." Psychiatrists and their patients have bodies.

8. I have pondered over the influence of a close friend, Ernest Southard, because of his uniqueness. When he took charge of the Boston Psychopathic Hospital in 1912 he was to my mind neither an administrator nor a psychiatrist. But he was a genius, a philosopher, a neuropathologist, a social worker ("Kingdom of Evils"), chess champion, philologist (a polymath which I had to look up in the dictionary), an intellectual playboy. Personally lovable, original, kindly, sensitive, the physicians who worked with him and under him felt a stimulation, a love and a respect which lasted all their lives. That Karl Menninger named his children's unit after Southard is typical. Southard brought other disciplines into psychiatry—he himself was always on the edges. If a member of my family had had a mental illness I should

have sent him or her to Dr. Barrett, Dr. Brill, Dr. Healy, Dr. Meyer or Dr. Salmon, I should not have chosen Ernest Southard ; the field over which his intellect and his fancies roamed was too wide.

Dr. Henry Bunker, in his chapter in *American Psychiatry, 1844-1944*, quotes Southard on the subject of Dr. Meyer. "I shall designate him as a ferment, a catalyzer. I don't know that we could abide two of him. But—we must be glad there was one of him."

In this statement about Meyer, Southard described himself exactly. Two of Southard would have been too much for anybody. His mind forever active, his head often aching ("too many thoughts crammed into one cranium"), physically he was one of the most inert men who ever lived.

Curiously, both Southard and Meyer proposed new classifications and new nomenclatures which did not displace conventional and older schemes but which aroused discussions and made people think.

And it was Southard and Meyer who in the 7 years we are describing laid the foundations for psychiatric social service.

9. And when I mention a little book by an Englishman that appeared in 1912 I recall playing tennis with him on a beautiful sunny day in his garden in Surrey. Bernard Hart showed in the title, *The Psychology of Insanity*, he was bridging a gap between old and new ideas. Hart made it easier for the psychiatrists who had always used a 19th century terminology to grasp the new ideas and words that the 20th century brought in. He tactfully introduced Freud's ideas in old words—he mixed asylum, complex, repression, lunatic ; "the de-

lusions of the lunatic resemble many of the beliefs that are held by the sane in the fact that in both cases the mental processes have a non-rational origin." A little book, but in over 20 editions a powerful one.

In summary, psychiatry from 1906 to 1913 was advanced by insiders (that is physicians who were practicing in "hospitals for the insane") and by outsiders (a bacteriologist, a physiologist, a patient who was a layman, a poorly prepared physician, a neuropathologist). This suggests that in the future psychiatrists should be ready to learn from all sorts and conditions of men.

All the important facts which I have recorded can be found in other places (*American Journal of Psychiatry*, Centennial Anniversary Issue, 1844-1944) but they are distributed in different chapters which do not call attention to their grouping—the remarkable septenate 1906-13 does not stand out. But in those 7 years teaching hospitals, orderly classification of mental illness, psychoanalysis, psychotherapy of a new sort, social service, lay mental hygiene societies and physiology and pathology began to pour their different streams into the main current of psychiatry.

A long view of American psychiatric history shows Colonial and early National sporadic hospitalization, then a long gap to the vivid decade of 1840-9, another long gap to a discovery of new sources of power in the 7 years 1906-13 and finally a half-century of the development of those sources to 1958. It is encouraging that after the grouping of new ideas early in this century there have been no doldrums but continuous and progressive motion—the impetus has not been lost.

RHYTHMS, CYCLES AND PERIODS IN HEALTH AND DISEASE¹

FRANKLIN S. DUBOIS, M.D.²

An earlier publication(1) presented a study of time from the psychological viewpoint and on the basis of the evidence offered, the suggestion was made that the sense of time plays a significant role in the motivation of human behavior. In carrying out this study it became apparent that not only the sense of time, but also a variety of recurrent phenomena related to time influence man in his adjustment. This paper is a review of current thinking in regard to certain of these rhythmic, cyclic and periodic activities and the role they play in health and disease.

The English words *rhythm*, *cycle* and *period* stem from Greek roots that mean "measured motion," "a circle" and "a going round" respectively(2). These closely related etymological origins support Webster's statements that all three are types of repeated occurrences organized in connection with time. According to Bills(3) "This organization is achieved by recurrence of one or more elements in such a way as to establish a perceptible periodicity." Such a "recurrence of one or more elements" is manifest everywhere in nature: the observed movements within the solar system, the ebb and flow of tides, the occurrence of day and night, the change of seasons, and the unseen rhythms of light, sound and electronics. Man is not excepted from such influences for there are recurrent phenomena within the human organism. Many of the physiological and psychological functions of man are modified by a "perceptible periodicity" of the biological processes.

PERIODICITY OF BIOLOGIC PROCESSES IN MAN

How biologic rhythms, cycles and periods originate and continue in man is not known but there is no doubt that they exist(4). Regular, repetitive variations of rest and activity are always present(5).

Body temperature usually reaches its highest point during the wakeful period of each 24 hours and its lowest during sleep(5). In addition, there are variations in individual diurnal temperature curves(6). Furthermore, Kleitman(5) has demonstrated that "morning types" of persons (those whose cerebration and performance are best shortly after arising in the morning) have higher body temperatures in the morning than at night while, conversely, "evening types" (those who feel and think best at the end of the wakeful period) have higher body temperatures in the evening. Similarly, there is a rhythm in the rate of the heart beat. Although this changes continually and is influenced by many factors, Kleitman and Ramsaroop(6) state that study of the heart rate during the day demonstrates a curve which is similar to that of the body temperature except for increase after eating.

Consistent diurnal changes have been shown to occur in the basal metabolic rate(7), the blood sugar level(8), the blood lactate level(9), the number of leucocytes in the blood(10), the hemoglobin, the hematocrit and plasma protein(11) and the urinary excretion of water, chloride and urea(12). There is even evidence to suggest that there is a distinct diurnal rhythm in the frequency of the onset of labor(13).

The menses of women are the best known recurrent biologic phenomenon, but it is not well known that there are rhythms related to many functions within each menstrual cycle. To mention a few: the body temperature goes down during the pre-ovulatory phase while after ovulation it goes up only to fall again just before the onset of menstruation(4). Surprisingly, the heart rate does not act completely parallel to body temperature(6), but the basal metabolic rate does, decreasing as the temperature falls and increasing as the temperature rises(14). Also, the electrical potential difference between the index fingers of the two hands changes, showing a rise in voltage in the preovulatory period that

¹ Presented at a meeting of the Vidonian Club, New York City, Jan. 26, 1958.

² Associate Medical Director of the Silver Hill Foundation for the Treatment of the Psychoneuroses, New Canaan, Conn.

reaches a maximum when ovulation occurs (15).

An interesting biologic rhythm is that of motor activity. Gesell(16) has shown that within the first two weeks after birth infants achieve a diurnal periodicity in their sleep-wakefulness pattern. As children grow, activity periods increase and rest periods decrease(17) until, as older children and adults, they effect a more or less optional pattern of activity largely governed by surrounding conditions and personality structure, but always on an individual diurnal basis.

Finally, it is noted that body growth varies with the seasons(18), the greatest increase in weight in growing boys occurring from June to December.

PERIODICITY IN HEALTH

From neonatal rhythms such as the heart beat(19) and those of eating, sleeping and waking established early in life, to the later developed rhythms that lessen fatigue and make for greater efficiency in living, man has organized his daily activities on the basis of repetitive patterns. Furthermore, his emotional life is nourished by his created rhythms of music, dancing and poetry. To these are added the periodic beauties of nature. Individually and as a member of a social group, man has made his life better and more effective by the utilization of both innate and acquired rhythms.

From earliest days men have realized that work rhythmically performed is easier, more quickly completed and more satisfying. As soon as men began to work jointly they devised rhythms that made for speed, ease of accomplishment and social enjoyment. The value of rhythmic activity in work which man found intuitively early in his existence has been confirmed by modern science. On the basis of critical tests, Griffith(20) states that the maximal speed of each individual's rhythmic pattern is his most efficient pace. Rimoldi(21) came to similar conclusions. His controlled studies demonstrate that "under the effects of rhythm the liberation of energy and regulation of work are more nearly perfect and less costly." According to him "Rhythm

reduces fatigue" . . . and "allows the mind to relax and busy itself with other things." Coleman(22) has shown that rhythm of movement is the most important factor in the development of endurance and delay of fatigue, and Walther(23) emphasizes that the application of rhythm to industry makes work less fatiguing and less monotonous. Thus men of long ago were right when they blended music, words and action in rhythmic harvesting songs for workers in the field and chanteys for sailors. Such melodies combined with work regulate the rhythmic expenditure of energy, adding not only to man's accomplishments but to his enjoyment.

The rhythm of music, poetry and the dance have contributed to man's well-being in still other ways. Hughes(24) believes that the heart beat was first transmitted into the drum beat for walking and marching and into a faster beat for singing and the measures for dancing. Terry(25) states that the internal rhythm of breathing and circulation are related to external rhythms such as the tides and the seasons and that man often expressed his conceptions of natural phenomena in spontaneous dancing. He used the dance to express emotions—fear, anger, love—and also to ward off evil spirits and to cultivate beneficent gods. There can be little doubt that the dance played an important part in maintaining emotional good health in primitive people.

As in the dance and music, poetry is based on man's inherent rhythms. Untermyer(26) says: "Poetry exists because there is in man the same sense of rhythm that dominates all life," and "the love of rhythm and a sensitiveness to the appeal of poetry is inherent in varying degrees in everyone." Long before children talk or comprehend words they respond to the rhythm of nonsense rhymes and of blank verse. It is the response to the rhythm of words that so often makes poetry a balm to the troubled spirit.

PERIODICITY IN PHYSICAL ILLNESS

Perceptible periodicity plays a part not only in health, but also in disease. From the time of Galen, physicians have been aware of the regular recurrence of certain illnesses, but it is only recently that earlier

reports and observations have been correlated and collected into a clinical entity now designated "periodic disease." Reimann(27) has assembled a group of apparently unrelated and collected into a clinical entity now current periodicity, "dependent upon or provoked by a single underlying rhythm." He points out that the disorders that make up this syndrome have in common "similar regular cycles of recurrence, combinations and substitutions of features, a genetic aspect, ineffectiveness of therapy and an unknown cause." Among such illnesses are periodic fever, periodic abdominalgia, periodic arthralgia, periodic neutropenia, periodic purpura, periodic edema and, possibly, such things as periodic paralysis, periodic vomiting and periodic ulceration of the oral and genital mucosa. It is Reimann's belief that the immediate cause of these superficially independent but genuinely related disorders is a vasomotor disturbance, the fundamental cause of the vascular change being unknown.

PERIODICITY IN PSYCHIATRIC ILLNESS

It has long been recognized that rhythmic, cyclic and periodic activities play a part in many of the phenomena seen in mental health and mental disease.

Almost 100 years ago Darwin(28) emphasized that "emotional expression belongs to rhythmical forms." Somewhat later Wundt(29) stated that rhythm has a large element of affective tone and that rhythm in emotions arises from feelings of expectation and satisfaction and that its continuance depends on repetition of tension. More recently Kubie(30) has said that this repetition of tension stems from the "recurrence of ungratified demands," that is, the recurrent delay or frustration of an instinctual urge. And Lourie(31) has demonstrated that this tension may be released in rhythmic motor patterns that seem to satisfy "an inner instinctual need" and "facilitate motor and ego growth and development in the infant." Thus it appears that rhythmic patterns are not only present in the emotional life of an individual but that they serve a useful purpose in the development and in the maintenance of good emotional health.

Coleman(22) states that all bodily rhythms have psychological significance

and that free emotional expression is rhythmic. He believes that rhythm and arrhythm induce different states of emotional feeling, thus suggesting that rhythmic processes play an active role in the psychological mechanisms of man. Hersey's(32) work on emotional cycles supports this view. He studied 25 "normal" people and demonstrated cyclical variations in their emotional tones. Each one had a highly individual cycle of regular highs and lows of mood. He noted that during the "high weeks" a person's drive toward activity was greater, that he felt well, anticipated pleasures, planned hopefully and was optimistic. Conversely, during the "low weeks" the same person found it difficult to muster physical and mental strength, had to push himself, concentrated with difficulty, preferred to sit quietly, found nothing very pleasant, was disturbed by minor crises, and was creatively unproductive. In short, life was something of a burden. This controlled study of "normal" people confirms the widely held clinical impression that *all* human beings function in terms of cycles of mood and that feeling tone varies not only from week to week and day to day but also from hour to hour. It also demonstrates that the periods and degrees of mood variation differ from person to person and must be carefully appraised and wisely considered in dealing with an individual's adaptive difficulties.

It is but a short step from such observations to a reaffirmation of Adolf Meyer's statement made in 1902(33) that "in psychiatry a certain periodicity of depression and excitement exists." The recurrence of attacks in manic-depressive psychosis are well known(34). Similarly, cycles of alternating "good" and "bad" behavior in psychotic patients have been mentioned in the literature(35) and periodic relapsing catatonia has been studied extensively(36, 37, 38, 39, 40). That such cyclic psychiatric disturbances are not rare is emphasized by Richter's report(41) that a study of the histories in the Phipps Psychiatric Clinic revealed over 250 patients with cycles in mood and behavior. From Richter's work it would seem reasonable to conclude that rhythmic activity occurs in practically all nosological psychiatric entities. Certainly

it is present in schizophrenia, manic-depressive disease and organic brain syndromes. Probably it is a component of certain behavior disorders in children (42) and possibly it contributes to the symptoms of the neuroses (30). Also, there is rhythm in the occurrence of peptic ulcer (43), of epileptic seizures (44, 45, 46, 47) and of familial periodic paralysis (48, 49). It is obvious that the phenomenon of periodicity plays an important role in man's physiologic and psychologic adjustments.

THE NATURE OF PERIODICITY

The late Alan Gregg (50) wisely said that he would welcome more rigorous studies of the mathematics of probability and would like to see physicians have a broader knowledge of rhythmic and cyclic phenomena. He pointed to the work of the Foundation for the Study of Cycles (51) and urged support of its program and of those who have like interests. Although modern research has not yet given a definite understanding of rhythms, cycles and periods, some facts have been authenticated and several interesting theories have been proposed. For example, Gjessing (36-40) has shown that recurring periods of abnormal thinking, behavior and mood occur irrespective of external events or conditions in patients suffering from periodic catatonia. He concludes from psychiatric and biochemical analyses that cycles of abnormal behavior are related to nitrogen metabolism and that the nitrogen balance shifts immediately preceding the change in psychologic state. Furthermore, he believes that at such times a toxin is produced which influences the diencephalon so that mental function is altered. The successful treatment of some of these patients with thyroid extract (52, 53, 54) which eliminates the swings in nitrogen balance, lends credence to Gjessing's careful work. However, other investigators do not consider such a metabolic disturbance of primary significance.

Richter (41) produced cycles of behavior and metabolism in rats by experimentally interfering with the functions of the thyroid and pituitary glands. He holds that the cycles brought about by interference with the thyroid depend primarily on "a

prolonged period of thyroid deficiency, which apparently produces secondary changes in the hypothalamus." Interestingly, and perhaps significantly, some of the experimentally-produced cycles were like those seen in human beings with periodic agranulocytosis, while others were similar to the disturbances of behavior and mood observed in catatonic schizophrenic patients. Like Richter, Lindsay (55) thinks that the primary factor in the production of abnormal cycles is a change in the hypothalamus, while others (54, 56, 57, 58, 59, 60, 61) believe the basic disturbance is an imbalance in the endocrine system.

Cole (62) postulates that an endogenous mechanism for inducing persistent rhythms may be the result of a particular hormone accumulating until it reaches some theoretical threshold that initiates a rhythm which simultaneously begins to exhaust the hormone. He also points out that rhythm-inducing factors may be exogenous in character; thus, periods of activity within the organism may be influenced by light, meteorological conditions, tides, phases of the moon and perhaps by cosmic radiation and the earth's magnetic field.

Peterson (63) also stresses the importance of such exogenous factors, especially meteorological conditions, in the production of biological fluctuations. He links sun spot activity and its effect on temperature and weather, which in turn influence body chemistry, with many periodic changes in the functioning and activity of human beings. He even relates solar activity to important historical events.

Finally, Reimann (64) emphasizes that certain authorities (22, 65, 66) regard rhythm as a fundamental law of nature and that this wax and wane of biologic processes may bring about the recurrent episodes of illness seen in "periodic disease." He points out that the most striking feature of the periodicity in these recurrent episodes of illness is the regularity with which they recur at intervals of 7 days or multiples thereof. For emphasis, he stresses that fever recurs at intervals or multiples of 7 days in certain patients with osseous tumors, leukemia and anemia (67); that arthralgia occurs at intervals of 7 days in bucellosis (68, 69); that Galen connected

the quarterly phases of the moon with the 7-day return of periods of fever; and that the menstrual cycle occurs at an interval of 4 times 7 each month. To explain this phenomenon of 7-day periodicity Reimann offers the fascinating conjecture that the rhythms of human life may be controlled by the solar cycle of 6.6 days, a thought that gains some status from the long-time historical and religious significance of the number 7.

SUMMARY AND CONCLUSIONS

In this review of rhythms, cycles and periods, reports are cited to support the view that both the physiological and psychological processes of man are influenced by recurrent biologic phenomena. Such periodic activities are basic ingredients in the behavior of human beings and actively influence man both in health and disease. Several theories as to the origin and perpetuation of these recurrent changes have been suggested but none has been completely validated. The true nature of rhythms, cycles and periods is a mystery and remains a challenge to future scientific investigations.

THE CHALLENGE OF RESULTS IN PSYCHOTHERAPY

IAN STEVENSON, M.D.¹

The tranquilizers have given psychiatry an unexpected by-product by forcing us to improve our evaluation of methods of treatment. These drugs exposed on a large scale the important influence through suggestion of new medicines which may also have powerful pharmacological properties. The firm establishment of the pharmacological efficacy of these drugs has required carefully controlled studies. In the literature of pharmacotherapy, accounts of soundly planned and executed research have almost entirely displaced the impressionistic reports based on "experience" which used formerly to fill the pages of psychiatric journals. We may expect that these standards will soon extend to the study of psychotherapy. As they have not yet done so, a brief review of the problem of results of psychotherapy may illustrate present shortcomings and point towards the needed reformation.

Although each year a spate of articles on psychotherapy pours from the press, an extensive search of the English literature on the subject showed that less than 75 articles on results of psychotherapy have been published in the psychiatric journals and about the same number in journals of psychology. Moreover, of these articles many merely deplored the paucity of results and did nothing to remedy it. Relatively few of the articles presented actual results of series of patients treated and of these even fewer met the minimal standards of excellence in research that we have grown accustomed to in, say, biochemistry or physiology or, among ourselves in pharmacotherapy. Few articles described carefully the patients treated or the method used; few included attempts at objective measurements of changes in patients and almost none included followup studies.

From the unsatisfactory, but available data we can reach several tentative conclusions, each of which will possibly require revision as we gather more valid data. First, large numbers of mental pa-

tients recover with little or no treatment in from 1 to 3 years. For psychoneurotic patients, for example, various studies show the percentage of such "spontaneous" recoveries to vary between 40 and 70% of the patients in the series (1, 2, 3, 4).

Secondly, comparisons of groups of treated and untreated patients have so far failed to demonstrate the efficacy of psychotherapy. The percentage of recoveries does not usually run higher in groups of treated patients than in those untreated. Eysenck has concluded on the basis of these comparisons, that a psychoneurotic patient has a slightly greater chance of recovering if he stays away from a psychotherapist than if he goes to one (5). However, he cannot prove this because the groups compared have perhaps not matched satisfactorily (6). Patients who seek psychotherapy from psychiatrists may have more severe illnesses than those who do not, many of whom recover spontaneously. On the other hand, social and economic factors seem to influence access to a psychotherapist more than the nature or severity of an illness (7), so possibly the compared groups do match. We cannot know without further study.

Thirdly, among rival kinds of psychotherapy comparisons again fail to show a superiority of one over another (5, 8, 9). Wolpe (10, 11) has published an exception to this pattern in his results with a large series of patients treated according to principles of learning theory and conditioning. He reports that between 85 and 90% of his patients became "cured" or "much improved" and contrasts this figure with the much lower recovery rates in patients receiving eclectic psychotherapy (9) and psychoanalysis (8), respectively 53% and 62% in the 2 series used for comparison.

That psychotherapy of various kinds or of our favorite kind, helps mental patients remains an important conviction of most of us. But with our present data such a conviction can hardly amount to more than an opinion among any who adhere to the principles of science. Many physicians of

¹ Department of Neurology and Psychiatry, School of Medicine, Univ. of Virginia, Charlottesville, Va.

the 17th to 19th centuries had convictions about the efficacy of phlebotomy, but who bleeds patients today? The history of medicine, and of our own specialty particularly, shows that personal conviction provides an insufficient basis for therapeutic action, especially when danger or expense occur with the therapy. Harm rarely comes from psychotherapy, but expense nearly always. Considering the millions of dollars annually invested in it by patients and psychiatrists, by teachers and trainees, that we have almost no satisfactory studies of its results is a major scandal of our profession.

We can explain our failure to study results and should perhaps try to do so, provided we do not use our explanations as excuses. In the first place, our profound ignorance of human behavior probably prevents us from distinguishing the more from the less fundamental changes in our patients. We often rely on observations of changes in symptoms while comparing these to the visible part of an iceberg; for the most part, we have not settled among ourselves the nature of what lies below the surface in psychopathology. Secondly, important behavioral changes occur slowly, certainly much more slowly than most of the changes an internist can observe after his therapies. Consequently, many patients we would like to study over a necessary period of observation disappear (often by moving to other communities) before proper followup studies have taken place. Thirdly, our emotional involvement with our patients often obstructs our evaluation of them. Most of us believe we could not treat them if we did not become involved emotionally with them, but we ought to recognize that this involvement often disqualifies us from evaluating the improvements of patients. Few parents think their children dull and few psychotherapists think their patients unimproved. Furthermore, our earnest desire to relieve human suffering makes difficult our asking a patient to wait for therapy while we appoint him a control subject. And if we do, he will probably seek help elsewhere. Finally, we must consider the least praiseworthy of our shortcomings in this matter, personal attachment to a particular theory and prac-

tice. As one improved tranquilizer succeeds another we can change pills without much change in ourselves. But to change psychotherapies requires changing our own habitual behavior. Perhaps it also means loosening affiliations with an adherent group of colleagues and even a decline in income from leaving a fashionable therapy for a successor not yet so popular.

Despite these obstacles without and failings within, we could study results of psychotherapy much more than we do and with less additional work than many may imagine when they postpone looking at their own results. Useful studies contributing some information, far better than the negligible data we now have, would not necessarily demand elaborate design. This brings me to attempt an outline of some requirements for a satisfactory study of results of psychotherapy.

The selection of patients for such a study first deserves attention. Ideally all applicants should receive psychotherapy, one portion receiving treatment by one method and another by another method, or perhaps less treatment. But we can rarely arrange matters so neatly. Then we must become aware of the reasons for selection. If we select patients who can afford treatment and turn away those who cannot, we will study a special economic group but at least we will know the basis of our selection. More harmful for research purposes are selections governed by other pressures, e.g., the apparent severity of the symptoms, or an "impression" on the part of the therapist that the patient will respond favorably. Such selections may make difficult or impossible the comparison of the group with other groups.

Next, we should record the kind and severity of each patient's symptoms, those of which he complains and those observed only by others. A therapist should say at the outset what he proposes to remove or improve. If the patient comes with the principal complaint of headaches, we should not consider him "much improved" if his headaches persist when the treatment ends. This simple precaution would put a stop to claims frequently heard to the effect that although a patient preserved his symptoms he had nevertheless "matured" or

"received considerable benefit" from his treatment. Such statements may contain truth, but this we can only know if their author describes his criteria for making them. The description of symptoms should include several topics of observation, *e.g.*, physical symptoms, subjective disorders of thought and feeling, and disturbances in personal relationships. Improvements in one of these parameters may accompany or even cause worsening in another (12).

The duration of symptoms deserves attention since this sometimes enables a patient to serve as his own control and sometimes shows the need for other control subjects with which to compare his treatment. For example, if a patient has unmistakably severe symptoms for 5 or 10 years, receives treatment for a year and subsequently remains well for a further 5 years, we have some evidence of benefit from the treatment, and this evidence multiplies when found in a series of 20 or 30 patients treated by the same method. On the other hand, when patients receive psychotherapy for 4 or 5 years for illnesses whose duration before treatment extended back only 1 or 2 years, we can say little about the efficacy of the treatment even when large numbers of patients recover under these circumstances. Such cases require for their evaluation a matched group of untreated patients as controls for spontaneous recovery.

A sound study of results should include also a description of the technique of psychotherapy used. Words like "psychoanalysis" and "psychotherapy" will not suffice because different authors have already applied them to widely varying techniques. We should learn the therapist's theoretical emphasis or emphases, *e.g.*, recovery of repressed memories, interpretation of the doctor-patient relationship, principles of conditioning, and how he acts with his patients to implement his intermediate goals. He should record also how often he and his patients meet and over what period of time.

We will probably progress more rapidly if we limit our categories of change in treated patients to two; namely, "cured or much improved" and "little or no improvement." To enter the first category a patient must at least have lost all or almost all the

symptoms which first brought him to therapy. He may have made other gains also, but must have made these. Since almost any patient gains something from contact with a friendly therapist, the categories of "slight improvement" or "moderate improvement" lend themselves too easily to the wishes of both patient and those treating and observing him. We may legitimately exclude patients who drop out early from a study although we should try to learn what happens to them afterwards.

Several persons should independently evaluate the changes in the patients. The therapist and the patient should certainly give their opinions, but we cannot always expect them to achieve the necessary objectivity for the task. The therapist's wish to succeed and the patient's wish to please may make them unwitting partners in a conspiracy to perceive more improvement than others can discern. The independent observations of members of the patient's family and of another professional person can greatly improve the evaluation of the patient's changes. Psychological tests have so far contributed little to measuring such changes (13), but continued study of their weaknesses may bring useful improvements.

Finally, apparent improvements brought about through fortuitous relief of life stresses or the transient but powerful effects of suggestion make followup studies essential to the evaluation of a technique of psychotherapy. Some followup studies of patients after relatively brief therapies, have shown further improvements in the conditions of patients compared to their conditions at the time treatment stopped (11, 14, 15). Such observations suggest the processes of spontaneous recovery already mentioned or the practicing and self-reinforcement with further benefits of new behavioral responses initially learned or stimulated in psychotherapy. But whether followup studies show relapses, maintenance of gains, or further advances in the patients, we cannot neglect them without hazard to the value of the entire study of results.

SUMMARY

I believe these simple rules within our means if within our desires. We should

hardly ask less of ourselves if we ask others to consider us scientists when we teach and practice psychotherapy. We can and should learn much about psychotherapy through other studies besides those of results. Yet we can only judge a therapy as therapy by its results and not by its attendant retinue of theories, however elegant and harmonious these may seem to be. Some years ago, Glover sounded a solemn warning on this matter with regard to psychoanalysis when he stated,

In my opinion, the main obstacle to the progress of psychoanalysis is the absence, first of reliable statistics of results, and, second, of any followup investigations. . . . Unless we know with some precision the exact limitations of psychoanalysis in different groups of mental disorder, we run the risk of providing new theories to explain away failures(16).

These reproaches apply equally to all kinds of psychotherapy. Their truth and the urgency which underlies them should stimulate us to remove the justification for them which derives from our continued neglect of the results of psychotherapy.

RELATIONSHIPS AMONG SEIZURES, PSYCHOSIS AND PERSONALITY FACTORS¹

EDWIN A. WEINSTEIN, M. D.²

The purpose of this paper is to call attention to some of the relationships among seizure content, inter-seizure behavior and personality background that exist in convulsive states. The neurophysiological observations of recent years have shown that epilepsy is associated with brain damage or at least altered brain function. While we cannot talk of a psychological cause of epilepsy, a psychiatric approach may still be fruitful. The seizure, the psychoses and other personality changes are indeed manifestations of brain injury much as are the changes in behavior associated with tumors, surgically induced brain lesions and the effects of ECT. In each of these, the alterations of behavior depend not only on the location, extent and rapidity of onset of the lesion, but on the social background of the individual and the situation in which the behavior is being observed.

The material was gathered from 50 patients hospitalized at the National Institute of Health for possible surgical treatment of seizures. They were admitted because their seizures had been resistant to medical and/or previous surgical treatment and because the clinical picture or EEG record had shown evidence of temporal lobe pathology. All subjects had EEG abnormalities reported as diffuse or localized to one or both temporal lobes. In some cases the seizures themselves were not severe or frequent but they had interfered with the patient working and otherwise existing in the community. Patients were hospitalized on a special ward housing mainly seizure cases. In most cases coming to the National Institute of Health was a kind of last chance and supreme effort eagerly anticipated by the patient and his family. In these respects we were dealing with a special situation.

The first observations concern the *aura*. This is, of course, a misnomer as the aura is not a breeze or warning but an integral part of the seizure. While the experience reported by the patient showed significant correlations with electrographic records it could not be understood simply as the physiological response to a specific cortical or sub-cortical area. Rather the experience is organized on a symbolic level where visual, auditory and other perceptual and amnesic elements take form in the context of a particular pattern of social relatedness. Whether a sensory aura is felt as painful, dead, numb or tingling depends not only on which nerve cells are activated but on the patient's habitual type of relating in the socially organized environment. One man had seizures in which he described painful sensations in his left limbs, as if they were being cut or twisted off, along with a feeling of deadness in them. For years he had worried about a chronically ill wife. He was fearful not only that she would die from her illness but that she would get run over or meet with a similar mishap whenever she left him. In interviews when asked about himself, he invariably got off on the subject of his wife's ailments and how often she had been close to death. In this case, the aura indicated not only a lesion in one of the cortical sensory areas but that the patient conceptualized a relationship in terms of violence and death. Patients who reported bad smells and tastes similarly described past experiences in traumatic terms and not only were the smells and taste disagreeable but they might hear and see threatening things. One woman had as her aura, a bad taste, a terrible odor and a feeling that someone behind her was going to grab her. This persisted despite two temporal lobe ablations. In telling the story of her life she described beatings by her father, the tragic death of her mother and an unhappy marriage to a brutal alcoholic. Not only was the past pictured in these terms but she also talked of her hospital experiences

¹ Read at the 114th annual meeting of the American Psychiatric Association, San Francisco, Calif., May 12-16, 1958.

² Bureau of Mental Health Services, Virgin Islands Department of Health, St. Thomas, V. I. Consultant, National Institute of Mental Health, Bethesda, Md.

in this way. When asked about her operation, she answered with an account of the drilling, cutting *etc.* Patients usually responded to this question with expression of appreciation for the surgeons and hopes for a cure.

Similarly when a scene from the past was visualized it was not simply a matter of the excitation of a particular group of cells in which the memory had been stored. The experience was a highly selective and condensed symbolic representation of current problems and relationships. For example, one patient repeatedly had a panoramic memory of a scene in his home town pictured in vivid detail. He was a person with a great attachment to home and family who derived his most significant feelings of identity in these symbols. In the course of 3 hospitalizations in each of which he had a craniotomy, the scenes differed in certain details which could be correlated with contemporary stressful events. Shortly before his second operation he saw the scene about his house as it was in actuality except that the path to his door was a purplish-red color. While awaiting his third operation he visualized the garage, a two story structure, with an additional third story.

Several patients had seizures concerning children. One girl could see a picture of her sister holding a baby. Another woman, as her spell began, would rush to hold her baby. These were persons who had derived their main sense of identity through the parent-child relationship, placing themselves or others in the role of a child, and expressing their own needs through their children. The patient who saw her sister holding a baby was a 15 year old girl very dependent on her elder sister. In these seizures the symbol "child" represents the patient's feelings about herself. In the course of recovery from an operation when one of these patients was reluctant and uncertain about leaving the hospital this attitude was seemingly expressed in the obsessive worry that something was going to happen to her child.

As the main component of their spells two women had urinary incontinence (on the whole this was uncommon even in a grand mal seizure). They showed so many

similarities in personality structure that a brief account of their behavior may be given. One was a 21 year old girl described as having been very prudish and resentful of men. Her seizures were completely controlled with medication but she developed sexually aggressive behavior, making advances to male patients. She became particularly involved with a boy with seizures from her home town. She also told stories of how her father beat her. The other young woman was described as highly critical of men and very self-conscious with them. She claimed that no man would marry her because of her seizures and insisted that even if she did get married she would not have children because epilepsy was hereditary. She did not develop a psychosis but the night after surgery had a dream in which a man that she knew had an operation identical to her own.

In each of these cases the occurrence of urination in the seizure seemed related to a stereotyped, sexually aggressive "masculine" orientation. What was striking in these two patients and others was the highly stereotyped and clichéd language that was used to relate experiences and characterize people. Parents were described as wonderful, kind and loving or terrible and cruel. One of the girls maintained "men are only out for one thing" and used this as a central focus in describing her relationships. There was a great deal of black and white, sin and virtue, God and Devil structuring of the environment.

Psychoses as defined in the conventional sense occurred in 12 patients during their hospitalization but remarkable or abnormal aspects of behavior occurred in almost all patients. This may be compared with Ervin, Epstein and King's observation that out of 28 patients with psychomotor seizures, 24 were diagnosed as schizophrenic and others as neurotic or having severe personality disturbances(1). In our group the psychotic reactions were of short duration and generally came on shortly after admission, following the withdrawal of drugs. As Gibbs, Epstein and his associates have pointed out, there tends to be a reciprocal relationship between seizures and psychosis. When the patient is psychotic he is

apt to be free of spells. In our patients too, most of the psychoses developed in patients without colorful subjective phenomena while those with complex visual and auditory experiences had a considerably lesser incidence.

Clinically the psychoses did not differ from schizophrenic and manic reactions, with catatonic and paranoid delusional types. A number of these passed through several stages. First the patient in his actions and words seemed to identify with big cultural stereotypes such as death, God and Jesus, the Devil, cure of cancer or epilepsy *etc.* Next there was a series of reduplicative delusions and misidentifications. Another patient might be called a cousin who had a cancer, or a nurse might be identified as someone who had died, or a doctor misrecognized as someone from home. In the third stage there frequently developed paranoid or euphoric attitudes toward the nurses and other patients. Thus, the nurse might be accused of treating them badly, or giving the wrong medication. Such a charge might be followed an hour later with loving praise of how wonderful she was. One man in his most confused state talked vaguely about racial miscegenation. He developed the idea that a negro and white staff member were married. Finally he expressed great appreciation and fondness for the care given him by a negro aide. A frequent maneuver was for the patient to make an angry charge against a nurse and then go back

and apologize at great length with many expressions of love and affection. Many patients who did not develop psychoses as such showed this kind of behavior repeatedly. Some were very withdrawn, remaining in their rooms in preoccupied fashion. It was of interest that following surgery these patients showed marked amnesic manifestations indicating a loss of relatedness in the environment expressed at a different level.

SUMMARY

In the seizure itself, in the psychosis which may develop, and in other verbal and non-verbal aspects of behavior the patient conceptualizes himself and his problems at different levels of interaction in the environment. The level of interaction is determined by the degree of stresses and/or the particular milieu of brain function. The content of the symbols or language that he uses is that which gives his experience the greatest and most vivid feelings of reality. All symbols take on form and meaning by reason of their place in a pattern of social relatedness and in the disturbance of consciousness associated with the seizure we become unaware of the patterning processes of language, how in language we selectively classify the environment and identify ourselves with cultural values.

PSYCHIATRIC ORIENTATION AND ITS RELATION TO DIAGNOSIS AND TREATMENT IN A MENTAL HOSPITAL¹

BENJAMIN PASAMANICK, M.D., SIMON DINITZ, Ph.D., AND
MARK LEFTON, Ph.D.²

It has long been apparent that the growth of a science of psychiatry awaits the development and acceptance of standard nomenclature and adequate criteria for determining the nature and types of psychiatric impairment. In view of the recent advances in other branches of medicine and in the physical and social sciences as well, it is almost inconceivable that psychiatrists are as yet unable, except in instances of relatively gross behavioral deviations, to distinguish between and define mental health and illness(1). The commonly promulgated definitions of mental health and illness are still so vague that they are frequently meaningless in practice.

It is equally unfortunate, and from the standpoint of actual practice, an even stronger indictment of the present state of psychiatry, that equally competent clinicians as often as not are unable to agree on the specific diagnosis of psychiatric impairment. Inter-clinician reliability on diagnosis has consistently been found to be low(2). Since hospitalization, course of treatment, case outcome, and research are all in large measure dependent on and related to specificity of diagnosis, the failure to expend more effort in developing adequate, specific and reliable diagnostic categories is a very serious matter. The lack of adequate diagnostic criteria not only impedes clinical practice, but frustrates epidemiologic attempts to arrive at the etiology of the various types of psychiatric impairment and at their incidence and prevalence. Any number of studies have indicated that psychiatric diagnosis is at present so unreliable as to merit very serious question when classifying, treating and studying patient behavior and outcome. The results of one such

study indicated that two-fifths of the diagnoses made in a clinic had to be revised one year after the discharge of the patients on whom they were made(3). In another study, it was found that different psychiatrists used different criteria as means of distinguishing between organic and psychogenic disturbances and between schizophrenia and the affective psychoses(4). Even in the only study in which it was suggested that satisfactory inter-rater reliability was demonstrated for some of the diagnoses, it was found that only 80% of the very gross classifications of a patient as organic, psychotic or characterological by one psychiatrist were independently confirmed by another. It was also found in this same investigation that when the specific subtypes of these disorders were considered, agreement between two independent raters occurred in only about half of the 426 cases studied(5).

This paper presents a wholly different approach to the problem of the reliability, and hence the validity of psychiatric diagnosis. It will be shown that the diagnosis of first admission cases in a psychiatric institute type of mental hospital over a 2-year period shows extreme variation by ward and equally great variations on the same ward, with changes in ward administration. These inter and intra-ward variations in diagnosis will be shown to occur despite the random assignment of patients to the various wards.

PROCEDURE

The study reported here was conducted at the Columbus Psychiatric Institute and Hospital. This institution provides voluntary admission patients with short term, intensive therapy, and is also a research and training center. It is an adjunct of both the Ohio State University Department of Psychiatry and the State of Ohio Department of Mental Hygiene. The institution contains 126 beds divided into 5 wards (3 female and 2 male) which operate on a

¹ This research is being undertaken by the Research Division of the Columbus Psychiatric Institute and Hospital and is supported by a grant (M 2940) from the National Institute of Mental Health.

² Columbus Psychiatric Institute and Hospital, and Departments of Psychiatry and Sociology, The Ohio State University, Columbus, Ohio.

largely autonomous basis. Patients are assigned to each ward on the basis of available beds and any selection which may occur in patient placement would result from the differential length of hospitalization on the various wards rather than through administrative policies. Since there is usually a waiting list for the female wards, bed space is at a premium and little, if any, selection in ward placement actually occurs.

This institution is heavily staffed with professional personnel and is the antithesis in most respects of the traditional custodial type of mental hospital. Each ward is supervised by a chief ward psychiatrist. In addition, there are 3 or 4 psychiatric residents, a clinical psychologist, 3 or 4 registered nurses, a social worker and an occupational therapist who comprise the clinical team. Interns, externs and trainees in the various specialties are also assigned to the several wards.

The study involved an analysis of the final diagnosis given to each of 538 female first admissions during a 2-year period, Jan. 1956 through Dec. 1957. All later admissions were eliminated to prevent the contamination in diagnosis which might otherwise have resulted. Special attention was devoted to the female cases since a greater variety of inter- and intra-ward analyses were feasible. Of the 538 female patients, 141 had been assigned and discharged from one ward which had been in existence for only 18 months. A second ward treated 206 patients in the 2-year period and the third ward 191 patients in this same time. On this latter ward, there had been a dozen ward administrators in the past 5 years and 3 during the past 2 years. Of the 3, one was responsible for 75 patients, another for 68 and the third for 48 patients.

RESULTS

The findings indicate that the female patients assigned to each of the 3 wards, and to each of the 3 administrators on the one ward, did not significantly differ from each other socially or economically. (Table 1) This would corroborate the known and stated policy of random assignment of patients to each of the 3 female wards. Ap-

proximately, 90% of the patients on each ward had been voluntarily admitted. Some 11% were Negro. Over half were housewives, 22% had been employed full-time prior to admission and the rest were students or were non-employed. Over three-fifths were married, 17% were single and 22% were divorced, widowed or separated. Some 22% had no more than a grade school education while 17% had received some college training. Most of the female patients were urban (86%) and Protestant (87%). The 538 female patients averaged 36 years of age (age range 14-75). The important point again is that on none of these social characteristics did the patients on the 3 wards or on the same ward differ significantly over time. Despite this, the diagnoses given these patients on both the 3 wards and on the ward which had had 3 administrators did indeed differ. Table 2 indicates that there was considerable inter-ward variation in 3 diagnostic categories. The percentage of patients diagnosed as schizophrenics varied from 23 to 36%; those diagnosed as psychoneurotic varied from 30 to 45% and those diagnosed as characterological from 12 to 22%. These differences, extreme and significant as they are, actually obscure as much as they reveal. As already noted, one of the 3 wards was administered by 3 different persons and their differential diagnoses tended to give this ward a broader spectrum of diagnoses than either of the other two wards.

The intra-ward variations over the 2-year period on the ward with the 3 administrators makes the point of differential diagnosis with greater impact. Table 3 indicates that two-thirds of the cases (32 of the 48) under the administration of Psychiatrist Z were classified as schizophrenics compared with 22 and 29% respectively under Psychiatrists Y and X. Psychiatrist Y diagnosed 56% of the patients as suffering from a characterological disturbance as opposed to 47% for Psychiatrist X and only 15% for Psychiatrist Z. It should again be stressed that the 3 administrators were dealing with the same type of patient; that they were training the same type of resident; and that they had equal access to the skills and approaches of the other members of their clinical teams.

This analysis of differences in diagnosis would be largely an academic exercise were it not for the readily documented fact that diagnosis is importantly related to hospital treatment and that both diagnostic and treatment practices are part of the general etiological outlook of the psychiatrist. Using data collected in 2 separate sub-samples—one year apart—the following relationships between diagnosis and other hospital and treatment variables may be specified with a modest degree of accuracy. 1. The length of hospitalization is definitely related to, though not necessarily an effect of, psychiatric classification. Table 4 indicates that hospitalization is most prolonged for female patients classified as schizophrenics and least so for those diagnosed as person-

ality trait disturbance (characterological) cases. Intermediate lengths of hospitalization are characteristic of psychoneurotic, affective and organic cases. Since some wards and administrators seem to cluster their diagnoses, there is also a considerable difference in the length of hospitalization by ward.

2. The utilization of specific forms of treatment such as electroshock or drug therapies are also clearly related to diagnosis. As noted in Table 4, none of the female patients classified as either characterologically or organically disturbed received ECT whereas one-fourth (4 of 15) diagnosed as affective (involutional) cases received a total of 30 such treatments and 4 of 47 patients designated as schizophrenic

TABLE 3
INTRA-WARD VARIATIONS IN DIAGNOSIS
BY WARD ADMINISTRATOR,

Organic	10	47.8		—	20.0	382 3.14

* Based on observations of the activities of patients on the wards and the percentage of observations during which the patients were found to be in psychotherapy session.

received 31 shock treatments.

Drug therapy prescription varied even more widely with diagnosis. One of 34 psychoneurotic patients was given Thorazine (16 days in all) whereas 23 of 47 patients classified as schizophrenic received chlorpromazine. These 23 received chlorpromazine for an average of 21.5 days. The remaining cases again occupied intermediate positions.

3. The percentage of patients in each diagnostic grouping receiving psychotherapy also varied considerably. These particular figures were difficult to obtain since no such record is available on the patients' charts. Instead, as a result of a study of ward behavior based on nearly 12,000 patient-observations, it was possible to arrive at the percentage of these observations during which patients in the various categories were receiving psychotherapy (6). These estimates are based only on observations conducted during the "working" day, and are exclusive of lunch, visiting, and evening hours as well as weekends.

The data indicate that under 2% of the 564 observations of affective patients were receiving psychotherapy whereas psychotherapy sessions accounted for 2.8% of the 2,111 observations of schizophrenic patients, 3.1% of the 382 observations of organic patients (2 were alcoholics), 3.4% of the 1,351 observations of those diagnosed as psychoneurotic and 5.4% of the 518 observations of the characterological patients.

DISCUSSION AND SUMMARY

These findings provide concrete statistical affirmation for the view that despite protestations that their point of reference is always the individual patient, clinicians in fact may be so committed to a particular psychiatric school of thought, that the patient's diagnosis and treatment is largely predetermined. Clinicians, as indicated by these data, may be selectively perceiving and emphasizing only those characteristics and attributes of their patients which are relevant to their own preconceived system of thought. As a consequence, they may be overlooking other patient characteristics which would be considered crucial by colleagues who are otherwise committed. This makes it possible for one psychiatrist to

diagnose nearly all of his patients as schizophrenic while an equally competent clinician diagnoses a comparable group of patients as psychoneurotic.

It is important to note, however, that these differences in diagnosis occur primarily with respect to cases not clearly or easily traceable to organic causes (*i.e.*, schizophrenia, psychoneurosis and character disorders). This obviously suggests greater opportunities for divergent points of view because of the lack of those objective criteria usually associated with diseases precipitated by some type of organic impairment. Whereas the latter can be more readily discerned with the aid of relatively reliable technical instruments (*e.g.*, EEG), schizophrenia, psychoneurosis and character disorders suffer the absence of such nosologic criteria. In addition, organically impaired patients usually exhibit behavioral patterns more clearly associated with organic malfunctioning whereas the more purely functional categories require more arbitrary and hence, less objective distinguishing criteria.

Schizophrenia is particularly exposed to an additional difficulty which makes it a less reliable diagnostic entity. This difficulty is linked directly to the differences in psychiatric orientations discussed above and is relevant specifically to the psychoanalytic point of view. It was discerned that the greater the commitment to an analytic orientation, the less the inclination toward diagnosing patients as schizophrenics. This pattern is traceable to two somewhat related factors intrinsically associated with the analytic position. On the one hand, these psychiatrists are less concerned with diagnosis *per se*; they tend to argue that a diagnosis places unwarranted restrictions upon a more "complete" exploration of whatever psychological mechanisms are at work or related, presumably, to a patient's illness. Secondly, is the more pronounced "liberal" philosophy espoused by this school of psychiatric thought which, seemingly, operates to create an inhibitory attitude toward "unnecessarily" and "unjustifiably" applying a label which seemingly has deleterious connotations and, therefore, apparently undesirable consequences for the patient so diagnosed.

Under present conditions, therefore, both diagnosis and the related care and treatment procedures tend to become more or less an adjunct of psychiatric orientation whereas the treatment program should be consequent on the diagnosis and a function of it. The alternative to present psychiatric classification problems should not, as some have suggested, be the elimination of diagnostic categories and the de-emphasis of classification procedures, but quite the reverse. What is needed is (a) a reconsideration of the means of eliminating the obvious biases connected with commitment to schools of psychiatric thought as an obstacle to the development of a taxonomic system of diagnosis, (b) increasing attention to the development of a standard nomenclature and (c) most important, emphasis on the development of objective, measurable and verifiable criteria of classification based not on personal or parochial

predilections but on behavioral and other objectively measurable manifestations. Until such time as these criteria are available, research on the incidence and prevalence of the various disorders and on their etiology, treatment, and prevention will continue to be hampered and impeded.

AGGRESSION, GUILT AND CATAPLEXY

MAX LEVIN, M.D.¹

Cataplexy can occur in the wake of an impulse of aggression. To be sure, the commonest precipitant of cataplexy is laughter, but aggression is not far behind. Since my first paper on "Aggression, Guilt and Cataplexy" (7) much additional material has come to light, and some of it will be presented here.

Aggression of any degree may be an effective stimulus, provided only it is associated with guilt. It may be overt, as in the common instance of the father stricken with cataplexy when he raises his hand to punish his child. It is no crime to punish a child, but the father is prey to conflicting emotions, and he is not exaggerating too much when he says, "This hurts me more than it does you."

The aggression may involve killing yet be socially acceptable, as when the hunter aims his gun or the angler hooks a fish. Though such killing is accepted by society, it can stir up feelings of guilt. Cataplexy has even followed the squashing of a bug (3) or the shooting of a dog out of the kitchen (8). Finally, the aggression may be that which expresses itself in sport. In some sports aggression is undisguised, as in boxing, where the aim is to hurt one's opponent. In others it is symbolic, as in baseball, where an infielder "kills" the baserunner by tagging him, or in tennis, where a man "murders" his opponent with a wicked volley.

The recent literature abounds with cases to illustrate all these points.

Cataplexy occurred in *fishing* in cases reported by Bonstedt (1), Dobin and Smith (5) and Yoss and Daly (15), and in *hunting* as well as fishing in the case of Thigpen and Moss (12).

Case 1.—A remarkable incident was reported by a narcoleptic in Nevada who has sent me a detailed account of his case. He has had attacks of cataplexy when hunting and fishing as well as from laughing. He reported the fol-

lowing incident: "One night after working late, I got home and when I turned the light on in the kitchen I saw a mouse running around the edge of the room. Thinking I could disable or kill it by hand, I picked up the nearest thing I could reach, a butcher knife, and headed for the mouse. When I got near the corner, I thought I had him trapped. I dropped to my knees and tried to strike him with the knife but my arms fell limp to my sides after one strike and I couldn't continue the 'hunt.'"

It has been said that hunting and fishing evoke cataplexy because they are so exciting. I submit that this explanation misses the point. There is little or no excitement when one squashes a bug, yet this sufficed to provoke an attack in the case of Brock and Wiesel (3). By contrast, there have been cases in which the greatest possible excitement failed to elicit an attack. In Bonstock's case (2) the patient had an attack when he got ready to fire at a duck but not when he tried to stop a runaway horse. This is a crucial case. In trying to stop a runaway horse—as exciting an undertaking as one can imagine—a man is not held back by guilt, as he is when he strikes his child or kills an animal, even if only a bug.

Another negative incident occurred in the next case.

Case 2.—A subway motorman began to have attacks of cataplexy at the age of 21. He has never had any sleep attacks. One day he was bringing his subway train into a station in the Bowery in New York. A drunk was lying asleep in the trough between the rails, and a porter was standing at the near end of the platform waving a broom frantically to flag the oncoming train. When the patient saw the porter, he immediately applied the emergency brake, and the train screeched to a halt *after* the first car had passed over the sleeping man. The patient saw the man as the car passed over. Though he knew the trough was deep enough to protect the man, he was greatly excited and tense, but did *not* have an attack of cataplexy. He proceeded without hindrance to take the steps necessary in the situation. This incident occurred at the age of 37. It was before he first saw me, and he was not on any medication at the time.

¹ From the Department of Neurology and Neurosurgery, the New York Medical College, Flower and Fifth Avenue Hospitals, New York, N. Y.

A significant negative observation was recorded by Daniels (1). The patient, a male epileptic, had once beaten up a man who had made fun of his sickness, and on this occasion he was not stricken with cataplexy. There is no guilt, hence no let or hindrance, when one punishes someone heartless enough to make fun of a sick man.

To turn to sports in which there is no real killing—in Thigpen and Moss' case (12) there was cataplexy in boxing and football as well as in hunting and fishing.

Case 3.—A policeman, born in 1916, began to have symptoms of narcolepsy in childhood. In addition to sleep attacks he suffered from cataplexy on laughing and on raising his hand against his children. He gave many examples of cataplexy in sport. **Boxing.**—In his youth the boys tried to interest him in boxing. He was a good athlete, and "I knew all the rudiments of boxing, but I could never get any pleasure out of it. I could defend myself but I could never be aggressive. I could never put any enthusiasm into hurting the other guy." He never had a clear cut attack of cataplexy in boxing, i.e. his knees did not buckle, but in the light of the history his inability to be aggressive is significant. **Football.**—From 18 to 21 he belonged to a football team. Three or four times, when chasing a runner whom he hoped to tackle, his knees buckled and he fell. "I'd sit there a few seconds and then I'd get up again." **Swimming race.**—In 1943 he and his wife and a woman friend were at a beach. The woman challenged him to race to the float (50 yards offshore) and back. An expert swimmer, he thought nothing of the short distance. "I raced out in fine style, but on my way back, about three-quarters of the way back, I just ran out of gas." At this time he was well ahead in the race. "I was banging away, and all of a sudden I just got weak, didn't have any power in my legs. I was barely able to make it to shore. I just about dragged myself out of the water and fell down on the beach. My wife asked me what was the matter and I could just about talk. I said, 'I don't know. I'm exhausted.'" He fell asleep on the beach and when he woke up he felt alright.

The patient and his wife were puzzled by this incident and blamed a glass of beer he had had before the race. Of course they were wrong. The imminent victory over his opponent must have triggered the attack.

Incidentally this man, who married in

1942 and now has 3 children, said that in the early years of his marriage orgasm always precipitated a cataplexy. He became limp all over and could not move or speak for a minute. Now, however (1958), he has coitus once a week without incident. Cataplexy on orgasm is well known (9).

In the realm of the milder sports, Swanton's patient had attacks of cataplexy when playing tennis, golf and hockey (11). Yoss and Daly (15), in a review of cases at the Mayo Clinic, found the case of a woman who had "reported that she could not play cards with her son because 'every time I get a good hand he can see my face sag.'" Any victory over an opponent, even if only in cards, may gratify unconscious aggressive drives and thus arouse guilt.

Important is the fact that in many cases of cataplexy it is aggression that has evoked the first attack. This is the more remarkable seeing that it is laughter that is the commonest precipitant of cataplexy. In Van Bogaert's case (13) the patient had his first attack of cataplexy when he reprimanded one of his employees. In Case 1 of Speirs and Speirs (10) the first attack occurred when the patient scored a direct hit in a snowball fight. In Case 1 of Wenderowicz (14) the patient, a farmer, had his first attack when he was about to whip his cow in anger. A week later the second attack occurred when he wanted to whip his horse. Next day he had his third attack in an argument with his brother. This patient had cataplexy on pleasant as well as unpleasant emotions, yet his first 3 attacks were evoked by aggressive impulses. In any seizure disorder the circumstances that evoke an attack are important, but those that evoke the first attack are doubly so.

It is plain that a display of aggression, when associated with killing or its symbolic equivalent, hence with guilt, may elicit an attack of cataplexy. We have here an example of conditioned inhibition (7). Conditioned inhibition occurs in man whenever we strive to suppress an impulse in circumstances which render it impermissible. Thus it is a natural impulse to run away from danger, but a soldier in battle must suppress it (6) and in these circumstances he may show clinical manifestations of inhibition. The simplest example of condi-

conditioned inhibition in nature is the dog that learns from painful experience that while it is generally safe to chase and tangle with small quadrupeds, it is not safe to do so if the animal is a porcupine. The conditioned inhibition that develops from this painful experience is the same in principle as that of the man who feels a pang of guilt when he raises his hand against his son. Of course there is a difference in the quality of the pain: the dog wants to avoid physical pain, while the man has a pang of conscience, but in either case an inhibitory impulse arises to check the positive impulse.

AGGRESSION MASKED AS PLAY

When cataplexy follows a display of naked aggression, as when a father raises his hand against his son, we may assume that the hostile impulse, being associated with guilt, evokes a counter-impulse, and the ensuing cataplexy is a manifestation of conditioned inhibition. This is also true when the aggression is only symbolic, as in tennis. The case is otherwise with the cataplexy that follows laughter, for this is a mystery and we do not know its pathogenesis. But there is one exception, the laughter that is interwoven with aggression. Some laughter is hostile, as in Zehr's Case 2, where the patient had an attack of cataplexy while laughing at a deafmute who was trying to express himself (16). In this instance cataplexy must have been of a piece with that which occurs in other aggressive situations.

Aggression may be playful. Play may serve as an outlet or vehicle of aggression, as one can see in the playground, where, for example, small boys make good use of their pistols. Two striking cases are submitted.

Case 4.—A narcoleptic woman of 28 began to have attacks of cataplexy at 17 and sleep attacks a year later. The initial symptom occurred when she played a practical joke on her sister Helen. Helen likes soft chewy candy and detests hard candy. There was a box of chocolates in the house and Helen reached for it, saying, "I'd like a nice soft piece." The patient said, "Here, take this one," pointing to one she knew had a hard center. Helen bit into it and made a wry grimace. The patient laughed and was about to cry "I fooled you" when suddenly "I got weak, my head dropped ;

I tried to cry out but all I could get out was a little squeak."

A devilish trick indeed, to deceive Sister into biting into a hard piece of candy. It would not rate high in a catalogue of sadistic behavior. But it sufficed to evoke an attack of cataplexy, one that proved to be the initial symptom of a narcolepsy. One is tempted to think that the motive force here was not the laughter, but rather the unconscious hostility concealed behind the mask of an innocent prank.

Case 5.—A man of 23 in Montana, who sent me an account of his narcolepsy, wrote: "When I run and play with my children, they need never fear that I'll catch them, for the moment I'm about to do so I collapse." The patient, chasing his children in play but handicapped by his susceptibility to inhibition, could not exercise aggressive impulses that were purely playful and succumbed instead to inhibitory counter-impulses.

SUMMARY

Cataplexy may be evoked by impulses of aggression associated with guilt. The aggression may be naked and undisguised as in hunting and fishing, and in boxing, where the object is to hurt and paralyze one's opponent. Or it may be symbolic, as in those sports where the object is to defeat the opponent, not to hurt him. Finally, it may only be that benign aggression that is expressed in practical jokes and some kinds of play. Cataplexy, in all these cases, is a manifestation of conditioned inhibition, a response to the guilt that attends aggression even when it is only unconscious.

THE PHYSIOLOGICAL BASIS OF THE TREATMENT OF DELIRIUM TREMENS¹

HENRY KRYSTAL, M. D.²

This study was designed to re-examine the rationale of the treatment of delirium tremens. Clinical observations as well as reports of other workers(1-3) suggested a particularly significant disturbance of the water and electrolyte balance, therefore a small pilot group was studied from that aspect. The attempt was made to integrate the psychological aspect of this complication of alcoholism with the data obtained by other techniques with the aim of establishing the physiological basis of the treatment of delirium tremens.

CLINICAL OBSERVATIONS

The group studied consisted of 700 patients with diagnosis of Delirium Tremens (D.T.) which represented all of the D.T. cases treated at the Detroit Receiving Hospital in the years 1954 through 1956. Of these cases, 82% were men and 18% women. Twenty-four percent were married. The ages ranged from the second through the sixth decade, with the majority between 30 and 60 years of age. Seventeen percent of the group were admitted to services other than psychiatric with a variety of illnesses, and developed D.T. only after a couple of days, as a rule. The mean duration of D.T. was 3 days, but the average hospital stay exceeded 5 days because of other illnesses. The frequency of those concurrent conditions was conspicuous. The following data were obtained by the review of 214 consecutive admissions of D.T. cases.

The patients had often been tremulous and insomniac for 1-2 days before admission. On the first day in hospital, 40% of the patients had hallucinations, 58% showed

	Number of cases	Percent of cases
Patients with clinical evidence of gastritis	86	40
Patients who had one or more illnesses other than gastritis	148	69
Incidence of individual syndromes:		
1. Infections	45	23
2. F.U.O.	5	3
3. Traumatic Injury	50	23
4. Liver disease (clinically)	24	12
5. Convulsions	18	9
6. Anemia	16	8
7. Chronic brain syndrome	6	3
8. Schizophrenia	6	3
9. Other illnesses	15	7

marked tremors, and 60% were uncontrollably anxious. Vomiting was noted in 40% of the admissions. Some degree of confusion and disorientation was found in all. On the second and third day, the percentage suffering of those symptoms fell markedly, but a considerable number showed *marked* anxiety, confusion, and tremors. Some patients admitted in "Impending D.T." became delirious on the second or third day.

ELECTROLYTE STUDIES

Electrolytes were studied on 45 consecutive men (ages 35-55), admitted in full-blown D.T., but without any evidence of liver failure or ascites. All these men were chronic alcoholics, many being actual "skid row" inhabitants. Electrolyte studies tabulated in the respective diagrams can be briefly summarized as follows:

1. *Sodium* (Fig. 1). The average of all determinations was below normal on the second, third and fourth days. The average then rose to the lower limits of normality. Although the averages were below normal (137 meq./l. on the first and second days) there was a wide span of results with some patients grossly hyponatremic.

Since all the patients received some sodium, and only very few (specifically 5 determinations) were above normal, one must consider the deficiency clinically significant. The wide range of results, how-

² Assistant Clinical Director, Detroit Receiving Hospital Department of Psychiatry; Instructor, Wayne State University College of Medicine; and Consultant, Committee on Alcoholism, City of Highland Park Board of Health.

FIGURE 1
SERUM SODIUM LEVELS OF D.T. PATIENTS
(EACH DOT REPRESENTS ONE DETERMINATION.)

FIGURE 2
SERUM POTASSIUM LEVELS

ever, indicates much individual variation. The lowest sodium results were 135, 132 and 134 meq./l. on successive days. Sodium deficiency may be suspected in the D.T. patient—but its severity has to be individually evaluated for accurate replacement. Serum chloride determinations closely paralleled the deficiencies of sodium.

2. *Potassium* (Fig. 2). In contrast to the sodium and chlorides, potassium averages tended to be either in high-normal, or above-normal ranges. Though the average was only slightly above normal only one test result was below normal, while a number of results were above normal. The highest potassium concentration reached 5 meq./l.

3. *Magnesium* (Fig. 3). Serum magnesium concentration was determined by the titian yellow colorimetric method: the normal range was between 1.3 and 1.9 meq./l. The magnesium averages were consistently low—with 1.5, 1.2, 1.3, 1.2 and 1.2 meq./l. on consecutive days. There was not a single determination above

normal, but many below normal. The lowest results were obtained on the second day: a serum magnesium of 0.99 meq. l. The absence of above normal magnesium levels, in contrast to the sodium or chlorides is explainable by the fact that saline was administered intravenously, whereas no magnesium was administered to this group.

4. *Hematocrit* (Fig. 4). Although only a small number of the determinations of the volume of packed red cells was performed, they make possible the following observations: The R.B.C. volume tended to be high (an average of 50% on admission). This finding is particularly significant when confronted with the previously reported high rate of anemia. Thus, the patients tended to show hemoconcentration on admission, but after therapy was started, the volume of the red cells came down to the normal limits.

DISCUSSION

Delirium is not a specific disease, but a disturbance of consciousness(3) which,

FIGURE 3
SERUM MAGNESIUM LEVELS

like the related condition of toxic psychosis may be caused by any physical or chemical influence which interferes with the metabolism or colloidal state of the brain. The development of delirium is favoured by the presence of diffuse brain damage, the existence of an unbearable reality situation, particularly in individuals with poor object-relations and reality testing. The above mentioned factors lead to the confusion. The anxiety-laden hallucinations of the D.T. patient reflect his terror in the face of his own aggression, so intense that it can only be handled by projection, and is experienced as endangering his life. The alcoholic's insatiable demands tend to threaten and "exhaust" his attending personnel who turn against him angrily and reject him. This behaviour serves both to "externalize" his aggression, and to act out the basic conflict of the alcoholic's life.

Although it has been conclusively demonstrated that a variety of underlying problems may lead to problem drinking (4, 5, 6), the formulations of Sandor Radó concerning the "pharmacothymic personality" (7, 8) have special pertinence in relation to the genesis of D.T. Based mainly on his work, and with some oversimplification of the problem for the sake of making

a generalization, the following observations are represented in Fig. 5. In the act of escaping depression and anxiety into a pharmacogenic elation, the addict gives up the reality-oriented regime of the ego, replacing it with a dependence on the drug. However, the euphoriant effect of the drug becomes diminished with the passage of time. The fact that alcohol, like all other drugs, loses this effect after a period of *continuous* use, and particularly in the presence of illness or "troubles" is not fully appreciated by physicians. When the alcoholic can no longer get relief from his anxiety and depression by drinking (a state commonly preceding D.T.) he is thrown into a rage and panic which he often describes as feeling abandoned by the "whole world." All his tenuous object-relations are experienced as sources of gratification, which alcohol supplies best of all, if only transiently.

In the resulting *pharmacothymic crisis* he tries to master his desperate state in one of the following ways: 1. Flight into withdrawal from the drug into a drug-free interval, thus restoring the potency of the drug; 2. Sadistic or masochistic acting out (explaining the conspicuous frequency of the alcoholics getting in fights—*cf.* the above reported incidence of traumatic in-

FIGURE 4
THE HEMATOCRIT DETERMINATIONS
(SHOWN IN VOLUME % OF R.B.C.)

any before admission: 23% of all cases);
 Psychosis. The psychosis may be an
 "alcoholic hallucinosis" or delirium tremens. It seems that the presence of physiological deficits, such as we have observed

(Figs. 1-4) favors the development of the latter. The pharmacothymic crisis represents a *great stress to the organism*. In delirium tremens, the multiplicity of deficiencies clouds the picture. In contrast, withdrawal symptoms attending narcotic addiction, can be seen to be a gross activation of the autonomic nervous system (with symptoms of either sympathetic or parasympathetic over-activity predominant), as well as the adrenal response to stress. If the latter fails, the narcotic addict shows a loss of weight, fall in blood pressure and other signs of adrenal deficiency.

Our next view of the patient in delirium tremens is also historical. As demonstrated above, 40% of patients in this series developed symptoms of gastritis before admission. Typically the patient lost his

appetite, and had a food intake often limited to alcohol and coffee or water for as long as 2-3 weeks, and for a variable number of days before admission suffered vomiting and all the other symptoms common to alcoholic gastritis and peptic ulcer. The systemic consequences of the vomiting are: 1. Loss of water; 2. Loss of electrolytes; 3. Inadequate intake of food, *particularly vitamins*. Water depletion alone results in symptoms somewhat different from those of combined water and electrolyte depletion (Fig. 6). Whereas loss of water alone results in dryness of membranes, fever and concentration of urine, depletion of water and sodium results mainly in symptoms related to hypovolemia, namely hypotension, oliguria, as well as muscle cramps(34).

Flink(9, 10), Suter and Kingman(11) show that in alcoholics with delirium tremens, there is a very high incidence of serum magnesium deficiency. This is confirmed by our findings, as shown above.

FIGURE 5

THE COURSE OF PHARMACOTHYMIA
 (FROM SANDOR RADÓ: *Psychoanalysis of Behaviour*, COURTESY OF THE AUTHOR AND GRUNE & STRATTON INC.)

What part of the symptomatology of D.T. may be due to magnesium deficiency can only be surmised on the basis of the following findings in experimentally produced magnesium deficiency in animals (9, 10): 1. Apprehension and anxiety; 2. Confusion; 3. *Muscular tremors*; 4. Delirium; 5. Peripheral neuritis; 6. Gradual increase in C.N.S. irritability with possible progression to convulsions, coma and episthotonos.³ Experimental and clinical evidence in magnesium deficiency produced in man by prolonged intravenous therapy shows that magnesium deficiency alone can produce symptoms thought to be part of delirium tremens such as anxiety, tremor and even delirium itself.

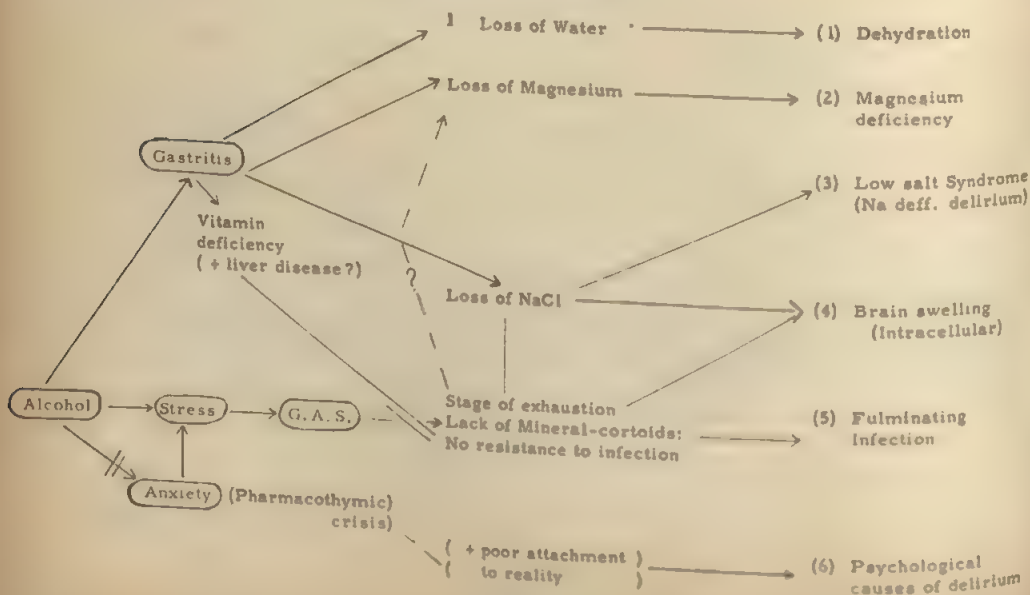

As is noted above, the alcoholic shows frequent clinical evidence of sodium depletion. With gastritis, vomiting, and poor food intake, sodium deficiency is marked, particularly so in hot weather. This fact alone probably accounts for the greater

³ Symptoms of magnesium deficiency, like that of calcium, are related to its concentration in the serum in an available form. Alcoholics may have chronic serum magnesium deficiency, which as suggested by animal experiments, may also cause peripheral vasodilatation.

mortality from D.T. in the summer months (12). Sodium deficiency in the range of 120-130 meq./l., has been shown to be associated with delirium (14). Although our determinations do not fall in ranges quite so low, there is possibly a potentiation of the deliriogenic effect by multiple deficiencies as observed in our patients, and particularly in the presence of brain damage. While gastritis is demonstrable in only 40% of our patients, 52% have sodium deficiency and 78% have some electrolyte depletion. The clinically noted severity of electrolyte deficiencies suggests that some other factors must be operating. For the answer to this question we have to look to the 60% of D.T. patients who have no antecedent gastritis. Those develop delirium often after a hospitalization for an organic illness or traumatic injury (27). We can now recall that 68% of all patients show other illnesses when hospitalized for D.T. Each of such illnesses imposes a stress on the patient's organism. Traumatic events often precede the onset of D.T. (*e.g.* the loss of a job or love object). When such a history is not obtainable it is the *pharmacothymic crisis* which constitutes the stress.

The chronic alcoholic, when subjected

FIGURE 6
THE PHYSIOLOGICAL DISTURBANCES FOUND IN
DELIRIUM TREMENS AND THEIR
POSSIBLE GENESIS

to stress, is unable to respond normally. He develops *hyponatremia* and *hyperkalemia* (Figs. 1, 2, 3) and is *unable to resist infections*, which very often spread to involve large portions of organs, and all too frequently become fulminating and deadly in spite of the use of antibiotics. In the current series of 700 patients, there were 16 deaths (2.5%). Five of these were caused by infections, in spite of adequate treatment with antibiotics. Of these 5, 4 had leukocyte counts of 7,000 or less in the presence of overwhelming infection such as pneumonitis or peritonitis. The patient's inadequate fibroblastic (inflammatory) response had failed to wall off the invading organism. These two phenomena (salt depletion and poor fibroblastic response) following a major stress suggest an inability to mobilize *prophlogistic mineral corticoids*(13).

Why the alcoholic reacts thus, is not definitely known. Research in this area seems to implicate vitamin deficiency(16, 17, 18), as well as the effect of chronic liver disease(21), chronic stress due to anxiety(20), and the direct effect of alcohol on the pituitary-adrenal axis(18). The impression gained by this study is that the alcoholic in D.T. has a normal or high level of antiphlogistic glucocorticoids but a deficiency of prophlogistic mineral corticoids. Flink's preliminary findings are compatible with such a state, as he reports high blood 17 hydroxycortisone in D.T.(22). A high cortisone, and low prophlogistic mineral corticoid level would be compatible with the electrolyte deficiencies, and lack of resistance to infection we observed—it would also favour peptic ulcerations—so common in the chronic alcoholic. D.O.C. (11 Desoxycorticosterone, a synthetic prototype of the prophlogistic mineral corticoids [14, 15, 18]) inhibits the anti-inflammatory effect of cortisone mol for mol.

As in an Addisonian crisis, the alcoholic in adrenal insufficiency may progress from hypo-osmolarity of the extracellular fluids to *intracellular overhydration*. This is the etiology of the pathological observation established as a fact for over 100 years: That the *brains of alcoholics in D.T. are often swollen when seen in autopsy*(25, 26, 27, 45). The brain encased in the rigid crani-

um, cannot expand freely when swollen. The result is an increase in intracranial pressure. Brain swelling produces the most serious and prolonged symptoms in this group of patients. It may produce convulsions, cause coma, and interference with vital functions. Initial nuchal rigidity may progress to opisthotonos. The patient, if not comatose, is constantly hallucinating, terrified and shows grasping or scratching motions of his hands. Cranial nerve palsy, transient, and fixed conjugate deviation have been observed. Once the brain swelling is fully established, it seems to subside slowly and the patient may be comatose or very sick for as long as two weeks, if he survives. As mentioned above, the total number of deaths among the 700 D.T. patients was 16, 5 of which were due to infection. Of the remaining 11 patients, 6 died of *causes not directly attributable to D.T.*⁴ The remaining 5 cases had clinical evidence of brain swelling (2 had autopsy confirmation). *When a patient dies of D.T. rather than with it—the cause of death is brain swelling or overwhelming infection.* Sceletch and Biefield, who studied autopsy results of patients who died of D.T. in 1916 (when the mortality rate was 75%) stated that the "constant autopsy findings" were "cerebral edema, narrowing of the yellow rim of the suprarenal gland (due to diminution of cholesterol content of the gland)—even to its complete disappearance . . ." (45).

CONCLUSIONS

The above considerations force one to view delirium tremens as having multiple determinations (Figs. 6 and 7) which result in at least 6 clinically recognizable etiological factors: 1. Dehydration; 2. Magnesium deficiency; 3. Sodium and chloride deficiency; 4. Brain swelling; 5. Fulminating infection; 6. Panic state (pharmacothymic crisis).

Good clinical judgment dictates that each of these conditions be recognized and treated *specifically*. The difficulty is created by the overlapping and "blending" of the

⁴ The causes of death of *these 6 patients* were as follows: 2 each, D.O.A.=not known, and liver failure, and one each due to pulmonary embolism and enterocolitis with hemorrhage secondary to chronic liver disease.

respective symptoms with the non-specific symptoms of delirium. Figure 7 was designed to review the diagnostic and management recommendations. It is self explanatory, and only a few points need further discussion. The analysis of our sample shows the correlation coefficient (r) between the sodium and magnesium serum levels to be -0.43 (Student's $t = 2.86$ indicating the correlation to be significantly different from 0 at the 1% level.) The cause for this inverse relation is not yet known, and needs further study. The emphasis, for the purpose of this discussion is on the necessity of separate and independent diagnosis of these electrolyte deficiencies, and the adjustment of therapy accordingly.

Magnesium is best replaced by intramuscular $MgSO_4$ 20-50% solution. As much as 8 gm. of magnesium per day, in divided doses may be given (9, 11, 25). Sodium and

chloride deficiencies have to be replaced, early in the treatment, intravenously, because of the vomiting. This is a reliable, and time-honored part of the treatment. At the same time, from the very beginning, vitamins are given, to enable the body to *reconstruct its enzyme systems*. Pending the resumption of normal adrenal function, signs of intracellular overhydration (particularly brain swelling) or infection are an indication for the administration of desoxycorticosterone acetate (D.O.C.)! A gradual withdrawal of the drug is necessary to prevent an acute relapse. In milder cases, the oral administration of syrup of glycyrrhiza (1 oz. t.i.d.) or ammoniated glycyrrhizin U.S.P. (4 gm./d.) is quite satisfactory. The active principle is the ammonium salt of glycyrrhizic acid, which has a mild D.O.C.-like effect (28, 29, 30, 31 and 32).

Cortisone is considered contraindicated

in delirium tremens. Its antiphlogistic effect may cause gastric hemorrhage, or cause infections to get out of hand (23, 24). There is also a possibility that cortisone, through the inhibition of phosphate reabsorption (33), may favor hypomagnesemia.

The last item in Fig. 7 is the problem of anxiety and insomnia. While it is usually necessary to use drugs for sedation of the disturbed patient, there is an important place for psychotherapy in the management of D.T. The impressions gained in this study are that the patient needs most urgently to reconstruct his reality testing *vis-a-vis* his terrifying aggressive wishes. The psychiatrist has, further, the function of helping the patient to own up to his great dependent needs. The demanding D.T. patient gains an opportunity to deal with those needs, if these are neither indulged indiscriminately and/or routinely nor rejected angrily thus paving the way for later outpatient psychotherapy. Reality-oriented psychotherapy may enable the patient to deal with the traumatic event that created the psychiatric emergency. The psychogenic aspects of D.T. need specific (psychotherapeutic) management, just as the other disturbances do. This can be augmented, *but not replaced* by the use of phrenotropic drugs.

In the treatment of drug withdrawal syndromes, including alcohol, it is necessary to distinguish the relief of the symptoms of withdrawal from the restoration of drug elation. The physician is obliged to relieve the symptoms of withdrawal, but the addict craves his lost euphoria. The consequence is that while his survival depends on the physician's understanding and treating the *physiological disturbance*, the alcoholic constantly demands a euphoriant drug. Paraldehyde is a case in point, where this demand is fulfilled without the doctor's awareness of it. Paraldehyde is a cyclic polymer made up of three molecules of acetaldehyde per molecule; 70-88% of it is metabolized in the liver by *depolymerization* to *acetaldehyde*, which is then oxidized to acetic acid (36, 37). Acetic acid has no effect on the brain (38). Acetaldehyde, however, is also the intermediate product in the metabolism of alcohol (41). Investigators in the field state that much,

if not all, of alcohol's effect on the brain—the *very action of intoxication*—is probably not an effect of alcohol, but of the acetaldehyde it becomes converted to (42, 43, and 44). With the use of paraldehyde we achieve the same effect as the clinicians of the past did with intravenous alcohol. We circumvent the gastritis and esophagitis preventing the alcoholic from getting large doses of alcohol, and supply enough acetaldehyde to produce a euphoriant effect. This is exactly what the addict does to himself in taking more and more of his drugs, until he becomes comatose. Thus the "modified pharmacothymic regime" of Fig. 5. As long as paraldehyde is being administered, the withdrawal from alcohol is not accomplished.

By far more dangerous, however, is the fact that the alcoholic sedated with paraldehyde ceases to have or complain of the symptoms of his physiological disturbances, and the doctor may neglect them. This takes an unfortunate toll in patients' lives. Of the 214 patients whose detailed chart study has been discussed, 145 were treated with several routines as they were admitted to various wards of the hospital. Every known treatment was used, including I.V. alcohol. Of those patients, 8 (5.3%) died. The remaining 69 were treated by the author, according to the principles of specific therapy as applied to D.T. in this paper. Not one of these patients died. Though this group is small, the results are statistically significant, even with provision for chance selection (Chi-square—5%), and compare favorably with the overall mortality of 2.5%. This improvement in results is not to be attributed to any one drug or procedure. The D.T. patient's chance for survival depends on his physician's application of the principles of *specific* psychiatric and physiological diagnosis, followed by *specific*, rather than a "routine" treatment.

SUMMARY

The current study involved the analysis of 700 cases of D.T., including a review of the causes of death of the 17 patients who succumbed to this illness. Forty-five patients were subjected to a study of their water and electrolyte disturbance.

Delirium tremens was found to be a

combination of a physiological disturbance and an emotional stress in an individual whose relation to reality is, at best, tenuous. The particular mental event precipitating delirium was felt to be the "pharmacodynamic crisis." The physiological disturbance was found to be *varied* and consisting of one or more of the following syndromes: 1. Dehydration; 2. Low serum magnesium; 3. Low salt syndrome; 4. Brain swelling. The last two, as well as the lack of resistance to infection, frequently found in delirium tremens, were assumed to be due to an inability to respond to stress. Owing mainly to a chronic vitamin deficiency, the alcoholic is unable to respond with the formation of desoxycorticosterone-like, prothogistic mineral-corticoids.

Methods of clinical diagnosis of the several physiological disturbances involved in delirium tremens were discussed, and suggestions were made to revise the management of this syndrome accordingly.⁵

ALCOHOL IN THE IROQUOIS DREAM QUEST

EDMUND S. CARPENTER •

Seventeenth century Iroquois used alcohol to stimulate their mystical faculties. The various configurations around dreaming and the vision quest, present in their culture long before liquor was introduced, quickly became associated with it.

References to this association are common in the early literature. The most interesting is *Historie de l'Eau-de-Vie en Canada*,¹ a treatise by François Vachon de Belmont (1645-1732), Sulpician missionary to Indians near Montreal. To him it was a moral problem. He adhered to the normal Christian view of man as unique among the inhabitants of the earth in view of his rational soul. Reason made him the link between heaven and earth in the ordered chain of the universe. Reason, moreover, was the divine part, by means of which human beings knew God: it showed itself in poised stature, grace of habits, beauty of speech, and—most important from the point of view of theology—in stability through virtue. True, he believed in apparitions of celestial personages to favored mortals, but only within the Christian scheme. To him, the drunken pagan was a man subject to continual insurrection from his irrational parts within, and to constant siege by Satan from without. That the pagan experienced visions, he didn't doubt, but that these dream visitors could do anything but harm, he refused to believe.

Indians, he wrote, held that through intoxication they would "experience a new sort of elation that promptly and effectively achieved the end of taking them out of themselves."² This belief had its roots deep in the vision quest. The active soul provided the means of understanding the will of spirits by revealing in dreams their wishes and how to satisfy them. Self-study, dream cultivation and submission to dream control were dominant ideas of the inner life. Dreams were induced by both personal and professional practices: seclusion,

fasting, meditation. The dreamer interpreted them first, then had them divined by another, thus indicating their external, not inner, origin.³

The problem was this: the Jesuits, like most Christians, assumed that only moral answers which recognized man as a collective animal had any validity, and were unsympathetic to the fact that the Iroquois conceived such answers in personal terms, and knew the only ones they would accept would come out of the dark night of the vision quest. Hence, unlike the Jesuits, the Iroquois didn't regard the temporary loss of mental control as sacrilegious—but on the contrary, believed that by getting outside the ordinary human order, they would get inside a higher spiritual order, and thereby more intimately in touch with reality. They pursued the conviction that extreme, fringe situations had more validity than normal, central ones; that there was more reality in experiences achieved outside established social patterns than in normal ones occurring inside of them. Striving for excess through ecstasy, frenzy, drunkenness, they were led to the adoption of emotional, intuitive tests as the yardstick. An experience producing a big emotional bang was a valuable one, and became less valuable as what it produced decreased in intensity. By this standard, a scream was more significant than a thoughtful statement, and violent drunkenness was more real and significant than controlled, restrained behavior, however much more creative it might be in the long run.

Later on, I think, the emphasis shifted to the use of alcohol as a release—to reduce anxiety and liberate aggression.⁴ But at this early stage, acting on the conviction that the drunken trance was a genuine metaphysical revelation, the Iroquois used al-

cohol to acquire spiritual power by stimulating mystical faculties "usually crushed to earth by the cold facts and dry criticisms of the sober hour . . . It makes him for a moment one with truth. . . This truth fades out, however, or escapes, at the moment of coming to . . . Nevertheless, the sense of profound meaning having been there persists."⁵

Sternly inhibited from any outward show of emotions by fear of retributory witchcraft, the 17th century Iroquois rode their emotions bareback under the protection of alcohol. Then in 1800, their prophet Handsome Lake, combining Quaker teachings with elements of the old faith, established the New Religion taught in the Long House today. In one version of his Good Message, 5 of the 130 sections are appeals for abstinence.⁶ Soon temperance groups formed within the faith. But in the first two centuries of contact with Europeans, there was little in Iroquois religion to promote temperance, and there was much to encourage alcoholic excess.

I believe this is an accurate summary of the position of the Jesuits, as revealed by their journals, and of the Iroquois, as revealed through the discerning, though prejudicial accounts of the Fathers. Neither, of course, had ever heard of Sigmund Freud or Social Work, but both had heard of God and spirits and so they thought and spoke in these terms, without recourse to words like reduction or catharsis. Their religion was the deepest thing in them. Its Dionysian features, common to many North American tribes, encouraged them to seek to attain, in their most valued moments, escape from the boundaries imposed on them by the five senses, to break through into another order of experience, to achieve excess in both ritual and personal experience, and to value the illuminations of frenzy, believing with Blake that "the path of excess leads to the palace of wisdom." The closest analogy to the emotions they sought was drunkenness, and so when alcohol was made available to them they gave it an honored role.

Missionaries and traders record that where liquor rations were limited, the Iro-

quois would unite their several portions in a common stock, which they would then divide among a few of their number, thus enabling them to attain that complete intoxication which, in their view, was the true end of all drinking:⁷

. . . when they [tribes near Montreal, 1671-1699] have only enough brandy to induce drunkenness for only one, if four are present, three will not even take a taste. But one will be chosen to have the privilege of becoming inebriated. Many say that they cannot become intoxicated on a single glass of brandy, that there is only one degree of drunkenness worth while, the sort which they call "Gannoniouraratonseri," complete insobriety. And when they begin to feel the effects of the brandy they rejoice shouting, "Good, good, my head is reeling." Then they begin to chant their "Gannonhaoury," into which they put all the evil which comes to mind.⁸

The fact that the Iroquois were not "ashamed of so infamous a vice"⁹ but took "pride in getting drunk and in making others drunk"¹⁰ for "to be drunk is to be valiant"¹¹ apparently suffering no hangovers,¹² increased the opprobrium. The Jesuits didn't seek to impose total abstinence¹³ nor did the English,¹⁴ but "Drunkenness, dreams and Impurity"¹⁵ were major obstacles to conversion;¹⁶ moreover, the Jesuits were clearly shocked.

Abbé Belmont begins with the observation that insobriety in Europe, which is "looked upon there as a mark of good-fellowship, a source of pleasure and comfort which friends and convivial companions allow themselves," should not be confused with Indian drunkenness which is "quite a different species of vice than what it is

⁶ Parker, 1912

among other people . . . a peculiar kind of insanity." He writes:

The Indians among the Savages were quite a different species than the same would seem among Europeans. For the Savages, having found a beverage which could so quickly and effectively intoxicate them, did not, like themselves, abstain from themselves and give them thereby the ability and the bravado they desired, it was not long before drunkards could be seen killing one another, husbands burning their wives, women disgracing their husbands, fathers throwing their children into burning caldrons.¹⁷

He continues:

They saved brandy until they have collected enough to make themselves drunk. Then they take to drinking without eating. For eating would check the effects of the brandy. When they feel their heads beginning to swim, they stagger and start to chant their death song into which they pour all their imprecations against their enemies. Once intoxicated, they throw off their clothing, or let it drop, and running about the town naked beat one another. They bite each others' noses and ears so that there are scarcely any features remaining. They run about howling with knives in their hands, their delight in seeing their women and children lying before them as if they were masters of the World.¹⁸

He then proceeds to list, with details, atrocities committed by drunken natives.¹⁹ Two centuries later, the details still make frightening reading.

This was no exception. In 1642 Father Richard wrote that the Iroquois "did not buy our liquors on account of any pleasant taste . . . but simply to become intoxicated".²⁰ while Father Carheil in 1665 said he was certain that Cayuga "drink only to intoxicate themselves, they say so openly, and sing their intention to do so, before executing it, and that they are heard to shout, 'I am going to lose my head; I am going to drink of the water that takes one's wits away.'"²¹

Alcohol was used for the cultivation of dreams; to the ancient rite of dream recitation was added the drink-all party: "Gen-

erally all Iroquois drink to intoxication, to themselves," wrote Noyan, "It has become the basis of the religion!"²²

"All that they dream," wrote Father Bruyas in 1668, "must be carried out."²³ Since dream commands weren't personal wishes, but divine orders, individuals weren't held responsible for acts committed in obedience to them.²⁴ Abbé Belmont, in a hypothetical dialogue between priest and pagan has the Indian say, "Drunkenness excuses everything."²⁵ Literally scores of cases are described by missionaries and traders where Iroquois who committed serious crimes enjoyed impunity because they were intoxicated at the time.

The *Jesuit Relations* are full of accounts of dream recitations and obedience to dream commands, as well as to the Iroquois interpretation of the experience of intoxication as equivalent to the dream experience. It's tempting to quote such cases at length for they are rich in detail and variation. But my point is simply this: to the Iroquois, intoxication originally meant not flight, but search; not escape, but fulfillment; not loss of self, but discovery of self. To them it was a positive, spiritual experience.

In later centuries they drank themselves into a stupor, not for the purpose of seeking out a guardian spirit, but because they were depressed—it was, they thought, a way out of their miseries. I think it might even be related to a "will to death." Surely this has been the opinion of most observers.

Thus the primary role of alcohol in Iroquois life changed over the centuries: the emphasis shifted from alcohol as the dream-maker in the 17th century, to alcohol as a release of tension and aggression in the 18th, and then to alcohol as evil in the 19th century—defined by the Prophet Handsome Lake, as the work of the devil. But the earliest interpretation was never wholly superseded and it may even persist to a limited degree among some of the modern Iroquois.

A STATISTICAL STUDY OF FIRST ADMISSIONS WITH PSYCHONEUROSES IN NEW YORK STATE, 1949-1951¹

BENJAMIN MALZBERG, Ph.D.²

In any one year a large number of patients are admitted to mental hospitals, but another group remains in the community. There is no general agreement as to the ratio of these two groups, though some estimates make them equal. Nevertheless, admissions to mental hospitals are so numerous that they have furnished the basis for most studies of the incidence and distribution of mental diseases. In the case of the psychoneuroses, however, the great majority remain in the community, and do not enter into any system of statistical reporting. Therefore, statistical studies of the frequency of the psychoneuroses are necessarily incomplete. Nevertheless, some useful information is available, if one considers hospitalized cases as representing the more severe and handicapping range of symptoms.

On this basis, we may consider the trend of first admissions with psychoneuroses to the New York civil State hospitals. These data are available since 1912. In recent years, such first admissions have averaged from 500 to 600 per year. In the early years, however, the totals were so small that it was necessary to average them over intervals of 3 years, in order to obtain significant results. Relative to all first admissions, there has been a significant increase in first admissions with psychoneuroses. The latter have grown from 1.5% of the total in 1914 to 4.3% in 1954.

The corresponding rates of first admissions per 100,000 population rose slowly between 1914 and 1930, then increased more rapidly to 3.6 in 1940. The rate dropped during World War II, but resumed the upward trend subsequently. Though it cannot be concluded from these data that there has been a relative increase in the psychoneuroses in New York State, it may be said

that such admissions to the State hospitals have increased, which is a fact of social importance in itself.

Who are first admissions with psychoneuroses? What are their characteristics, and from what elements of the general population do they come? Answers will be sought through a consideration of such first admissions to all hospitals for mental disease, public and private, in New York State, from October 1, 1948 to September 30, 1951. The middle of this period, April 1, 1950, was the date of the federal census of population, and this permits us to compute average annual rates of first admissions. The data refer primarily to white first admissions during this period.

There were 3,472 white first admissions with psychoneuroses. Of this total, 1,664, or 47.9%, were admitted to the civil State hospitals. An equal number were admitted to the licensed hospitals. This is in marked contrast to the relative distribution among all white first admissions during the same period. Of the latter, 78.9% were admitted to the civil State hospitals, and only 18.4% to the licensed hospitals. The difference resulted in large part from the higher economic status of psychoneurotics, which made private facilities more available to them. There is also a selective process, however, whereby the private hospitals are less likely to admit patients with psychoses associated with advanced age. But even first admissions with dementia praecox are underrepresented among admissions to the licensed hospitals, as they amounted to only 15.7% of the total of such admissions, compared with 47.9% for psychoneurotics.

LEGAL STATUS

Closely related to the question of the relative frequency of admissions with psychoneuroses to public and private mental hospitals is the type of admission procedure. Thus, of all white first admissions during 1949-1951, 61.1% were admitted by judicial certification. Only 19.4% made voluntary applications. Among the psychoneu-

¹ This investigation was supported by a research grant from the National Institute of Mental Health, of the National Institutes of Health, of the United States Public Health Service.

² Principal Research Scientist, Research Foundation for Mental Hygiene, Inc., Albany, N. Y.

otics, however, only 17.2% were certified judicially, whereas 67.1% were admitted on voluntary application. The difference is due primarily to the admission policies of private hospitals, whereby voluntary application is given preference over other forms of admission. It is also true, however, that psychoneurotics have, generally, a better understanding of the value of voluntary application.

AGE

There were 3,576 first admissions with psychoneuroses (both white and non-white) to all hospitals for mental disease in New York State during 1949-1951. Two-thirds of the admissions were aged between 20 and 44. The average age was 38.2 years. The average ages were 39.0 and 37.6 for males and females, respectively.

The average annual rate of first admissions was 8.0 per 100,000 population. The rate rose to a maximum of 16.1 at ages 30 to 34, and declined steadily at higher ages. Males and females had similar trends, the rates rising to maxima in early adulthood. Males reached their maximum rate about 5 years earlier than females. However, the rates were generally higher for females than for males at all ages. The average rates were 9.1 and 6.9 for females and males, respectively. The excess of the rates for females was relatively greater at ages under 40.

The several types of psychoneuroses varied in their age distributions at first admission. The oldest were those with hypochondriasis and those with reactive depressions. Among the whites, these groups had median ages of 48.3 and 39.9 years, respectively. The others were grouped closely with median ages varying from 32.2 among those with hysteria to 35.9 for the mixed category.

ENVIRONMENT

The average annual rate of first admissions with psychoneuroses during 1949-1951 was 8.3 per 100,000 white population. The urban population (defined as those living in incorporated places with a population of 2,500 or over) had a rate of 8.9. The remainder of the population, which was considered rural, had a rate of 6.3.

Unlike the experience with other groups of mental disorders(1), New York City had a lower rate than the other urban areas. Since the several areas and types of population differ with respect to admissions, it is necessary to use standardized rates. These also show that urban populations had higher rates than rural populations, and New York City had a lower rate than the remaining urban population. It is probable that New York City, with a concentration of private psychiatrists, sends a large proportion of psychoneurotics to such facilities, as a result of which they do not count as first admissions to mental hospitals. It is also known that New York City includes certain populations which recognize only to a limited degree the need for treatment of psychoneurotic conditions(2). How large a correction should be made for these factors in the rate for New York City is not known.

ECONOMIC STATUS

First admissions to hospitals for mental disease are classified with respect to economic status as follows(3):

Dependent—Lacking in the necessities of life or receiving aid from public funds or persons outside the immediate family.

Marginal—Living on earnings but accumulating little or nothing, being on the margin between self-support and dependency.

Comfortable—Having accumulated resources sufficient to maintain self and family for at least four months.

On the basis of such definitions, it has been found(4) that first admissions with mental disorders of organic origin include low percentages with comfortable economic status. Among first admissions with general paresis and alcoholic psychoses, the percentages were 11.1 and 10.1, respectively, during 1949-1951. Among arteriosclerotics and seniles they were 13.2 and 9.8, respectively. This increased to 18.7 among first admissions with dementia praecox. All were low, however, in comparison with the percentages for involutional psychoses (32.0) and manic-depressive psychoses (38.9). First admissions with psychoneuroses were comparable with the latter groups. A third

of the psychoneurotics were classified as in comfortable circumstances.

However, these statistics, though suggestive, do not give conclusive evidence of a relation between economic status and the frequency of mental disease. This requires, in addition, a similar classification of the general population, which, however, is not available.

Another approach may be made by a consideration of occupation, to which economic status is closely related. The census of 1950 classified the employed population by age and occupation. First admissions were classified similarly, but there is undoubtedly a degree of misclassification, since census enumerators and hospital staff did not always classify in the same manner. Furthermore, the tendency to hospitalize varies among psychoneurotics, so that we may expect a large proportion of the economically affluent to be treated privately. Nevertheless, males in professional categories had a high rate of first admissions with psychoneuroses, as did farmers and farm managers. White females of the professional class had a high rate, whereas operatives and domestics had relatively low rates.

Considering the degree of reliability of such data, it appears justifiable to conclude that, on the whole, they substantiate the belief that the psychoneuroses are relatively more prevalent among the higher economic classes.

EDUCATION

Previous investigations have shown that, in general, the rate of first admissions to hospitals for mental disease varies inversely with degree of education. An exception was found in the case of the manic-depressive psychoses, where those with the highest degrees of education also had the highest rate of first admissions(5). To the latter group we must now add the psychoneuroses.

The federal census of 1950 classified the general population by education, according to the highest grade completed. Because the highest grade was unascertained for a large percentage of first admissions, the latter were grouped into 4 classes: no education, elementary school, high school and college. The average annual rates of

first admissions for 1949-1951 were computed for those aged 25 years or over, because formal education may be regarded as completed by that age. The average annual rate increased steadily from 6.1 per 100,000 among those with no formal education to 16.8 among those with some degree of college education.

Since the relative frequency of the psychoneuroses varies with respect to age and sex, the rates were recomputed on the basis of a standard population, aged 25 years and over. Thus, for constant sex and age proportions, the average annual rate increased among both males and females from a minimum among those with no education to a maximum among those who had attended college.

It appears, then, that first admissions with psychoneuroses, like manic-depressive psychoses, come from a higher social level than other groups of first admissions. It is sometimes asserted that this is a statistical illusion, deriving from the possibility that members of a higher social class may receive a more favorable diagnosis. We do not have the data necessary for assessing the weight of this argument. It is doubtful, however, that such an interpretation can be applied to the large numbers who are admitted to the State hospitals.

MARITAL STATUS

As with other groups of mental disorders, there are significant differences in the rates of first admissions with psychoneuroses, when they are compared with respect to marital status. In general, the unmarried have a higher rate than the married. The highest rates as might be expected, occur among the separated and divorced. The rate for the widowed appears low, when compared with the single and married groups. This results from the different age distribution of the widowed population. When standardized, the rate for the widowed is higher than that for the married, and is on a par with that for the single.

It is probable that the psychoneuroses act selectively with respect to marriage. Severe disorders will reduce the probability of marriage. With advancing age, the unmarried (single) population is left with a higher proportion of the unstable. Conse-

quently, the relative excess of rates of first admissions among the single is greater at ages beyond 35. This progressive action by selection is limited, however, to males. Apparently, marriage is less of a selective factor among females, in accordance with principles which make the male the more active partner.

The high rates of first admissions among the separated and divorced are indicative of the emotional instability of large sections of these groups.

RACE

There were 3,576 first admissions with psychoneuroses, of whom 3,472, or 97.1%, were white. Of the remaining non-white group, 92 were Negroes. Because they constitute so large a part of the whole, the characteristics of the white first admissions differ only slightly from those for the entire group of first admissions with psychoneuroses. Thus, the average age of the white first admissions was 39.3 years for males, 37.8 for females, and 38.4 for both sexes. The average annual rates per 100,000 corresponding population were 7.1 for males, 9.6 for females, and 8.3 for both sexes.

The 92 Negro first admissions with psychoneuroses represented only 1.5% of total Negro first admissions, compared with 6.8% among whites. They were younger than whites, the average ages being 30.9 for Negroes and 38.4 for whites. The average annual rate was 3.3 per 100,000 Negroes, compared with 8.3 for whites. Whereas white females had higher rates than white males, Negro males had higher rates than Negro females. Differences in average rates between Negroes and whites cannot be attributed to differences in age or sex proportions of the corresponding populations, because, when standardized for age and sex, the average annual rates were 10.8 for whites and 3.7 for Negroes. Furthermore, when limited to New York City which included 81% of the Negro population of New York State, the standardized rates became 9.4 for whites and 3.2 for Negroes. It is clear, therefore, that the relative rate of first admissions with psychoneuroses was higher for whites than for Negroes. However, the question inevitably arises as to whether Negro psychoneurotics are hospitalized as readily as whites. This is not a

question of prejudice with respect to admission to hospitals, which does not occur in the New York State hospital system. There is a strong probability, however, that Negro psychoneurotics may carry on more easily in their own communities, and that tolerance for them is greater. If so, this would account in part for the lower rate of such first admissions among Negroes. Similar social factors, operating more intensively among Negro females may explain their lower rates of first admissions with psychoneuroses than Negro males.

Other than a classification of the population by color (*i.e.*, white, Negro), the federal census does not give any more detailed descriptions. Thus, though white first admissions to mental hospitals in New York State are described in broad ethnic terms, there is no corresponding classification of the general white population. This makes it impossible to compute rates of first admissions for some large groups in New York State, such as those of Irish or Italian origin.

Some differences are apparent, however. Thus, whereas 6.2% of all white first admissions during 1949-1951 were diagnosed as psychoneurotic, the corresponding percentage for Jews was 10.4. For Irish and Italians, the percentages were only 4.8 and 5.1, respectively.

For the white population of New York State, the average annual rate of first admissions with psychoneuroses was 8.3 per 100,000. The Jews were estimated conservatively to represent 15% of the white population of New York State in 1950(6). This implies a population of 2,080,000 Jews in 1950. There were 853 Jewish first admissions with psychoneuroses, which gave an average annual rate of 13.7 per 100,000. The rate for the remaining non-Jewish white population was 7.4 per 100,000. Consideration must be given to the fact that the vast majority of Jews in New York State live in New York City. There were 741 Jewish first admissions with psychoneuroses from New York City, which gave an estimated average annual rate of 11.8 per 100,000. There were 870 white non-Jewish first admissions, giving an estimated average annual rate of 5.8, only half that for Jews. This confirms the oft-repeated statement that Jews have

a higher incidence of psychoneuroses than non-Jews.

It has been suggested, however, that part of their excess results from a greater willingness by Jews to seek medical advice, and, in particular, to a more favorable attitude towards psychiatry and psychiatrists. A lesser frequency of statistical reporting of the psychoneuroses by other groups, such as Irish and Italian, is attributed in part to contrary attitudes(7). However, this does not alter the probability that Jews have a higher rate of psychoneuroses than non-Jews.

NATIVITY

Of the 3,472 white first admissions with psychoneuroses, 2,899, or 83.5%, were native-born and 573, or 16.5%, were foreign-born. The average age of the native-born was 37.0 years. Native white males and females had average ages of 37.8 and 36.5 years, respectively. The foreign-born were much older, males having an average age of 46.6 years, females an average of 44.9 years. The average for both sexes was 45.4.

Native whites had an average annual rate of 8.5 per 100,000 corresponding population. Foreign whites had a rate of 7.6. For each sex, the foreign-born had a lower rate. The rates were influenced, however, by the differential distribution of the two populations with respect to age. The native-born are relatively more numerous at the younger ages (i.e., under 40), where the specific age rates are high. The foreign-born are weighted at the older ages, where the rates are relatively low. When the rates were standardized with respect to age and sex, using the population of New York State on April 1, 1950, aged 15 years and over (in 5 years intervals) as standard, then the rates became 11.2 and 12.1 for native and foreign-born, respectively. A further correction may be made by limiting the comparison to New York City, since the foreign-born population is predominantly urban. On this basis, the standardized rates become 9.5 and 11.7 for native and foreign-born, respectively. This indicates a higher rate of first admissions with psychoneuroses among the foreign-born.

Unlike the psychoses, more cases of psychoneuroses are treated privately, and therefore do not enter into statistics of hos-

pital admissions. It is probable that this has a greater effect upon the statistics of the native than upon the foreign-born. Hence, to an unknown degree, the rate of first admissions with psychoneuroses is underrated among the native-born.

It may be noted that the standardized rates for New York City are less than those for the State as a whole. New York City has a heavy concentration of psychiatrists and of clinical facilities. This is generally supposed to increase the number of recognized cases of mental disorders, including psychoneuroses. Other things equal, we should have expected higher rates for New York City. As pointed out previously, certain population groups do not encourage the treatment of psychoneuroses. These groups are concentrated heavily in New York City, and hence tend to reduce the rate of such first admissions.

MIGRATION

It has been demonstrated that rates of mental disease, as measured by first admissions, are higher among migrants than among non-migrants(8). The census data for 1950 make it necessary to use place of birth as an index of migration. Thus, native whites, born in New York State and resident in New York State in 1950 may be considered as non-migrants; those born elsewhere in the United States but resident in New York State in 1950 may be regarded as migrants.

On this basis, the difference in average annual rates of first admissions with psychoneuroses between migrants and non-migrants in New York State during 1949-1951 is well marked. For males, the rates were 6.4 per 100,000 for non-migrants and 11.6 for migrants. The corresponding rates for females were 8.6 and 15.6, respectively. For both sexes combined, the rates were 7.4 and 13.7, respectively.

Since migrants are younger than non-migrants, the rates were recomputed on the basis of a standard population. On this basis, the corrected rates became 11.6 and 8.4 for migrant and non-migrant males, respectively; 15.5 and 10.7 for the corresponding female populations; and 13.7 and 9.7, for both sexes combined. Thus, the rates for migrants remained in substantial excess.

SUMMARY

Though they undoubtedly constitute one of the largest categories of mental disorders, the psychoneuroses represent a small proportion of hospitalized cases. It is common knowledge that many psychoneurotics, even without treatment, carry out their social obligations. Others are treated privately, and therefore do not enter into hospital statistics. But of the unknown total of psychoneurotics, some, because of the severity of symptoms, are hospitalized. The records of the New York State Department of Mental Hygiene show that first admissions with psychoneuroses to the civil State hospitals have grown to approximately 4% of the total first admissions, and represented a rate of 4.3 per 100,000 population in 1954. As an indication of their social status, it may be noted that almost half are admitted to the licensed hospitals, in contrast to only 20% of all first admissions.

First admissions with psychoneuroses were admitted to all mental hospitals in New York State at an average age of 38.2 years. The average annual rate was 8.0 per 100,000 population. The rate rose to a maximum of 16.1 at ages 30 to 34. At all ages, females, generally, had higher rates than males.

Urban populations had higher rates than the rural populations. It is significant, however, that New York City had a lower rate than the remaining urban population. This was due, in part, to several large aggregates of population in New York City, who do not encourage treatment for what they consider minor disorders.

In general, only a small percentage of first admissions are described as being in comfortable economic circumstances. A third of the psychoneurotics, however, fall in this category. The only other comparable groups are those with involutional psychoses and manic-depressive psychoses. Some support for this conclusion is found from rates of first admissions according to occupation. Groups high in the occupational scale appear to have high rates of first admissions with psychoneuroses.

The higher social status of psychoneurotics is also seen through a consideration

of degree of education. Thus, only 15% of all white first admissions, aged 25 years and over, had been to high school or college, whereas these degrees of education had been attained by two-thirds of the first admissions with psychoneuroses. In fact, 20% of the latter had been to college. The rate of first admissions among psychoneurotics was higher for those with some degree of high school or college education than for those with no education or only elementary education.

With respect to marital status, the highest rate of first admissions occurred among the divorced, followed by the separated. The lowest rate occurred among the married.

The rate for Negroes was approximately a third of that for whites, despite the fact that the total rate of first admissions for Negroes is greatly in excess. It is not known at present whether the lower rate for psychoneuroses represents a racial characteristic. It is probable, however, that hospitalization for psychoneuroses is less likely to occur among Negroes, because of the greater tolerance exercised by the Negro community in this respect.

Jews have a higher rate of first admissions with psychoneuroses than the remaining non-Jewish white population.

Native whites residing in New York State, but born in other states have a higher rate than native whites born in and residing in New York State. This is interpreted as showing that migrants have a higher rate than non-migrants.

VALUE AND LIMITATIONS OF A PSYCHIATRIC DEPARTMENT IN A GENERAL HOSPITAL IN BOMBAY (INDIA)

N. S. VAHIA, M.D.¹

We have reviewed the work of the psychiatric department of our hospital which was established in 1947, to determine what has been accomplished.² The annual admissions did not increase materially until 1950, but since then the increase has been remarkable: from 212 in 1950 to 1,914 in 1955. Diagnostic classification (1950) is shown in Table 1.

The wide variety of cases indicates a remarkable desire on the part of the patients' family doctors to send them to a general hospital. Also, the value of such a variety of cases for teaching undergraduate and post graduate student is very evident. Admission of psychiatric cases in this hospital is limited because of the small number of beds allotted to us. "Reactive Psychosis" represents cases in which psychosis was precipitated by severe mental strain in the immediate past.

¹ From the Department of Psychiatry, K. E. M. Hospital, Parel, Bombay, India.

² My thanks are due to the Superintendent, Thana, for giving necessary data from the mental hospital and to the Dean of the K. E. M. Hospital, Bombay, for allowing me to use the records of the hospital for this paper.

The duration of illness is shown in Table 2. This shows that although the need of such a department is well appreciated by the medical profession and the public, the need for early detection of psychiatric illness in order to get better therapeutic response is not well appreciated by them. Illness "since birth" represents some of the mentally retarded children.

Almost half the cases coming to the department have been referred by other departments of the hospital (Table 3) showing the realization amongst other specialities in medicine of the need of psychiatric evaluation in many of the cases coming to them.

Although the ratio of male to female patients in the outpatient service is about 2 to 4, the ratio for the psychiatric department is 5 to 3. Whether this higher incidence in females is due to inequality of the social status of women in our country is very hard to say. The number of children attending the department is less because they go to the child guidance clinic in our sister institution Bai Jerbai Wadia Children's Hospital.

TABLE I
TYPES OF CASES

Types	Number of Cases			
	1950	O.P.D.	Indoor	Mental Hos.

Miscellaneous	61	292	4	239
Total	237	1914	93	1036

Treatment.—It was difficult to evaluate our therapeutic efficiency from our records because the cases that were given symptomatic treatment such as hypnotics could not be properly followed up. Those that were given drugs like Dexedrine, Largactil or Rauwolfia alkaloids also have not been carefully followed up because of lack of sufficient cooperation from patients. Only the cases that received "special" treatments have been comparatively well recorded. It must be stated that the results recorded here were those at the time the treatment was discontinued because in the absence of psychiatric social service, satisfactory follow-up of the patients was not possible. One outstanding item noted by us was the remarkably small number of cases receiving these special treatments, compared to the much larger number in need of them. This was mainly due to the shortage of staff and number of beds.

Psychosis.—On the whole, psychoses were treated with ECT, cardiozol convulsive treatment and insulin treatment. Analysis of insulin coma treatment results have not been included here as this paper is mainly based upon outpatient work. Insulin sub-coma treatment was given in the outpatient department not only for psychosis but also for other cases. The details of this work

have been published in a previous paper. The response to these treatments is shown in Tables 4, 5 and 6.

Psychoneurosis and Other Mal-Adjustments.—Patients with psychoneurosis, psychosomatic illness and other maladjustments were given superficial psychotherapy together with drugs like methedrine, pentothal and carbon dioxide, which would reduce the length of psychotherapy so that a greater number of patients could be taken. The results are presented in Table 7. The results have been further analysed according to the drugs used as an aid to the psychotherapy (See Tables 8, 9 and 10). We were impressed by the fact that our results were poor compared to those when we had a full time trained psychiatrist for this work previously.

COMMENTS

1. The data show that a psychiatric department in a general hospital is better placed than a mental hospital, not only for the treatment of patients with psychosis but for those with psychoneurosis, psychosomatic illness and other maladjustments who would not usually go to a mental hospital.

2. The medical men, at least in the bigger cities, in our country seem to be aware of the need of psychiatric help for patients

coming to them with psychological or somatic complaints. Amongst other specialties also, the need to study the psychiatric factors is gaining more recognition.

3. Although drugs like Largactil and Rauwolfia alkaloids to a certain extent have decreased the need for physical treatments

in psychosis, the demand remains great for these treatments. The discrepancy between the demand and our ability to keep pace with it was most marked in cases that needed psychotherapy. This had increased the burden on the psychiatric department particularly because by its very nature psy-

chotherapy is a time taking procedure and the personal attention that every patient requires is hard to provide in absence of sufficient staff.

Lately, we have been able to provide facilities for group therapy. We are studying its value but it is too early to present our impressions.

SUMMARY

1. Considering the stigma associated with mental hospitals, the psychiatric department of a general hospital is a much better place, not only for detection and treatment of early cases of psychosis, but also for various kinds of psychoneurosis.

2. As a much wider variety of cases of

psychiatric illnesses attended the psychiatric department of a general hospital it is a good place not only for diagnosis and treatment of these illnesses, but also for teaching purposes.

3. Importance of psychiatry as an integral part of general medicine is well recognized by general medical practitioners and also by specialists in other branches of medicine; at least in the larger cities in our country. What is probably not appreciated is the need for early recognition of these cases and for treatment in the early stages to obtain better results.

4. Limitations of this department were very conspicuous in this study. A greater

number of trained personnel and more beds are urgently needed for both treatment and teaching purposes.

5. In our country, the establishment of psychiatric departments in general hospitals with adequate staff and beds is urgently needed to serve the community more efficiently and to develop healthy attitudes towards mental illness.

CLINICAL NOTES

CLINICAL EVALUATION OF TRIMEGLAMIDE IN ANXIETY

ROBERT A. BRAUN, M.D., AND PAUL LOWINGER, M.D.

The recent discoveries of drugs with considerable effect on symptoms of mental distress have stimulated the search for other drugs in this field. One such compound is a central nervous system depressant, Trimeglamide (3, 4, 5-trimethoxybenzoyl-glycine diethylamide). Preliminary studies indicated that this compound is unique in one aspect: practically all drugs which produce sleep in humans cause ataxia and flaccid excitement during induction in dogs and cats; however, Trimeglamide induced somnolence and sleep in these animals without such motor disturbances (1). It therefore appeared that this compound might be of value for humans as a sedative and hypnotic in the treatment of insomnia, tension and anxiety states.

A study of the effects of this drug was made in the following manner: Patients referred to the psychiatric outpatient department for evaluation or treatment were given a complete psychiatric examination. Laboratory and other studies were performed whenever indicated. Those patients who were likely to benefit from drug therapy through periodic outpatient visits were then referred to our drug clinic, based on certain criteria as outlined by Lowinger *et al.* (2). All these patients experienced overt anxiety as a major symptom. At their first drug clinic appointment some of them were selected at random for treatment with Trimeglamide. Others were placed on this medication who had not previously responded satisfactorily to other drugs in the same clinic.

Twenty-one patients who took Trimeglamide from 7 to 100 days are all included

in this study; the mean duration of treatment was 39 days. The age of the patients ranged from 20 to 62 years; 9 were male and 12 female. The diagnostic groups were: psychotic disorder, 4 (schizophrenic reaction, 2; involutional psychotic reaction, 1; manic-depressive reaction depressed type, 1); psychoneurotic disorders, 8; psychophysiologic disorder, 1; personality disorders, 8.

The patients received 500 to 1,500 mg. of Trimeglamide daily in divided doses. They were followed in our drug clinic by return appointments every 1 to 4 weeks. At each visit the physician determined the patient's degree of disturbance using 5 criteria: anxiety, sleep, depression, thought disturbance, and interpersonal relations. A scale from 1 (no disturbance) to 5 (very severe disturbance) was used. This made it possible to obtain a score by adding these ratings. In addition to this more objective evaluation, a note was made at each visit describing all symptoms, especially those suggesting toxicity, and the dosage adjusted according to the clinical response of the patient. The drug was discontinued when there was a lack of improvement after an adequate trial or when the patient refused to continue taking the medication.

The effectiveness of Trimeglamide in each patient was determined on the basis of the alleviation of symptoms. The ratings for disturbance on each of the 5 criteria (anxiety, sleep, etc.) were totaled at the end of the observation period. If these ratings were lower, this was considered as a slight or marked improvement; if it was the same or higher, it was interpreted as no improvement. In addition to these scores, the clinical notes were used in the evaluation of the patient's progress. The following results were obtained: complete relief, 0; marked improvement, 2; slight improvement, 2; no improvement, 17.

Symptoms or complaints referable to

¹ From the Lafayette Clinic and Wayne State University College of Medicine, Detroit, Michigan. This investigation is part of a project supported by Research Grant MY 2241, National Institute of Mental Health, Public Health Service. Riker Laboratories, Inc., Northridge, California, assisted this study and furnished the Trimeglamide (3, 4, 5-trimethoxybenzoyl-glycine-diethylamide), also identified as Riker 548.

There were always 10-15 persons, 100-150 chickens, 10-15 and 20-30 pigs, sometimes having had one pig, but continued on the day for a meal or 10 days. The modification in a second period was occasionally done to compensate the group at a "bad" season. The first appeared again at the next fall time. A third period comprised a "disaster" and a year for the first time after the continued drying the population had to close and had a substantial decrease. A fourth period after had been on the way for 4 months and on 1-10-1979 the weather became clear developed an early September and was beautiful for a period of 2 weeks. The illness was considered most likely to be caused by virus although there were some unusual features. The diagnosis of being influenza A virus was also confirmed.

POTENTIATION AND FACILITATION OF INSULIN COMA THERAPY

J. B. HAYES, M.D., and ROBERT E. KENNEDY, M.D.

one of the most difficult problems in a well-balanced budget is the allocation of the available funds within the optimum limits of safety. There are several variables in the treatment program that have to be considered at all times: 1 The maximum amount of insulin that may be given to the patient. 2 The production of ketone bodies in some reactions with more than the maximum amount of insulin allowed. It was felt that the production of some ketones in a minimal amount of insulin would increase the inherent risk of IHD, and a study was begun in 1958, now reported, in an attempt to solve this

For the purpose of this study, Teflon has been used extensively in this institution since its introduction into the psychiatric field several years ago, and has appeared to have a

potentiating effect when used with other therapies. During the past year, all the female patients receiving IST obtained satisfactory reactions on a minimal amount of insulin but many of the male patients on the same treatment showed no effect even when receiving our maximum amount of 900 units of regular insulin daily. It was found on closer observation, that the female patients also received perphenazine in conjunction with their daily insulin dosage and that this was not true in the cases of most of the male patients. As a result of this observation, all of the patients on IST after this time (1958) were placed on perphenazine, usually in the amount of 4 mgs. q.i.d. for the female patients, and 8 mgs. q.i.d. for the males. We noted an immediate response to this combined treatment, and were able to produce the desired coma level in all patients, using as little as 25 to 35 units of regular insulin on each daily dose. Coma levels were classified as described by Kalinowsky (1). A further test of this hypothesis was made when a second course of insulin therapy was given to a male patient who previously had shown

[illegible][illegible]

no response, failing even to after 3 months of daily treatment with 100 mg. of insulin. During the second stage of treatments, this patient also received 8 mg. of perphenazine q.i.d., and the dosage was always under 300 mg. He has just completed a course, with no reactions, with marked improve-

ment. As a further aid in IST, we have now begun the use of Glucagon² (2) using 0.5 mg. intramuscularly to the patient 10 to 15 minutes before we wish the treatment terminated. This drug is given at the second stage of coma reaction, and in most cases, the patients awake in from 10 to 15 minutes, and are alert and able to take care of themselves and drink orange juice. It was found, however, that if the patient had gone past early second stage of coma, the drug was ineffective, and then he must be given an intravenous injection of sugar solution.

The problem appears to have been solved by the use of perphenazine in conjunction with insulin. The coma reactions reached in the usual amount of time (2½ to 3 hours), but then there ap-

peared to be a plateau in the reaction, and the usual dosage of insulin was not enough to break through this plateau. It was found that if the patient was given a further 10 mg. of perphenazine in a matter of a few minutes, this had a powerful effect and the first observation on the next of the treatment was to find the reaction at the second stage of exactly the same intensity of an injection of sugar.

In summary, it is felt that the glucose combination of doses in conjunction with insulin produces a fast reaction even in insulin-resistant patients, which is apparently as safe as the use of insulin alone, but with the advantages of increasing the number of patients who can benefit from this treatment, without raising the risk of the procedure or increasing the number of hospital personnel required for the treatment program.

CLINICAL RESULTS WITH THE USE OF DEANOL (DEANER®) IN SCHIZOPHRENIA

VERONICA M. PENNINGTON, M.D.¹

Deanol (2-dimethylaminoethanol) is an important psychochemical compound. It is thought to be a precursor of acetylcholine (1), will partially substitute for choline (2), and is a complete substitute as a growth factor in growing chicks (3). It has been shown to slightly depress the hippocampus (4), to depress reticular stimulation (5), to block the interaction response between reticular formation and hippocampus (6). The potentials of reticular formation are increased and barbiturate induced depression of the reticular formations is overcome (6), and the resistance of the heart to pentobarbital is doubled by deanol (7).

We began our study with 30 institutional-

ized patients in April, 1957. The dosage range was 5 mg. to 25 mg. twice daily, and the drug was not given after 3 p.m., so as not to interfere with sleep. Shortly thereafter, the number of patients was increased to 100, all institutionalized females, with age range 26 to 82 years. All were schizophrenics, exhibiting apathy, retardation and depression. Many were mute and inaccessible. The dosage of deanol ranged between 25 mg. and 400 mg. daily, the period of therapy was from 2 to 9 months. Some patients were markedly lethargic from use of reserpine, chlorpromazine, trifluopromazine and perphenazine; in these patients deanol was used to combat the lethargy.

The medication was given orally, in-

¹200 East Meadowbrook Rd., Jackson, Miss.

intramuscularly, or intravenously, parenteral therapy being utilized when the patients refused oral therapy. We tried intravenous therapy merely as a test to determine the time required for effect. Since deanol is essentially replacement therapy, rapid onset of action is not a necessary requirement. Other analeptic drugs, such as methylphenidylacetate hydrochloride, d-lysergic diethylamide, *etc.*, are more effective when administered intramuscularly, but, for most patients, sustained action is desirable, and can be obtained by oral administration of any efficient analeptic drug(8).

The criteria for improvement were increased interest in surroundings, and work capacity; decreased mutism; improvement in retardation and depression, and improvement in personal care. There was significant improvement in 20 of the 100 patients. A decrease in somatic delusional trends was also noted. Lethargy and somnolence due to reserpine, trifluopromazine, perphenazine and Dartal were relieved in 25 of the 100 patients.

There was no significant difference in the reactions of 10 nonpsychotic as compared to psychotic patients. When indifferent response was noted with daily dosage up to 200 mg., increasing the dose up to 400 mg. daily did not improve the response significantly. This was true equally for psychotic and non-psychotic patients.

There was no loss of weight in any of the patients. Side actions seen in 5 patients, consisted of jerky movements of the extremities and head, staring, restlessness, and insomnia. The blood pressure of one patient changed from 120/80 to 140/50; this patient had taken 10 mg. t.i.d. for 5 days, and the Deaner was discontinued because of hypertonia of the neck musculature.

Anorexia was not noted: instead, appetite was increased in 33 patients.

The purely analeptic effect of methylphenidylacetate hydrochloride, iproniazid and pipradol is more marked than that of deanol.

SUMMARY

Deanol was used in 100 institutionalized female schizophrenics. It was moderately effective in 25%, producing increased interest in milieu, work and recreation, and decreasing somatic delusional trends, depression, retardation, and mutism. Side actions were minimal, and all were controlled by dosage regulation.

A NEW SCREENING TEST FOR BROMIDE INTOXICATION

GEORGE H. REYE, M.D. AND JOY R. JOFFE, M.D.¹

The admission to Northern State Hospital within a single month of 2 patients subsequently diagnosed as acute brain syndrome, bromide intoxication, made ap-

parent the need for a simple screening test for bromism. On admission both patients were totally disorganized and so seriously ill that transfer to the medical service was mandatory. The diagnosis not immediately apparent in the first patient, was only suspected when symptoms of toxicity claimed

¹ Respectively, Director of Research, and Chief of Medicine, Northern State Hosp., Sedro Woolley, Wash

the physician's attention. The initial serum bromide levels were 412 mg.% and 385 mg.% respectively. On appropriate treatment, both patients completely recovered.

The routine determination of serum bromide levels would insure proper diagnosis. However, they would impose needless demand on the limited laboratory service available in most state hospitals.

Urine was selected as the medium for testing: 1. Bromides are principally excreted by this pathway; 2. The established admission urine could be utilized. Initially, a urine bromide screening test using gold chloride, the reagent in the serum bromide test, was evaluated. This was discarded when a considerable number of false positive reactions were obtained, principally from phenothiazine drugs. Subsequently, a simple, accurate screening test was developed that involves the conversion of the bromide ion to free bromine. The free bromine is then extracted and concentrated by either Toluene or chloroform. These extracting agents, being nonmiscible with water, form a definite layer in urine. The presence of bromine and hence bromide is determined by an orange to reddish color in the extractant. To date, after extensive testing with this reagent of urines of patients on a wide spectrum of medications, no false positive reaction has been observed. Iodides will react but when extracted, a definite violet rather than the orange color is obtained. It was noted that this reagent is almost as sensitive as that employed in the Thorazine Test(1) for the detection of Thorazine and Sparine in urine, and similar colors are obtained. No confusion exists, however, when Thorazine and bromide are together in urine as the converted bromine is extracted and concentrated in the usual fashion.

The specific reagent used is acidified potassium bromate, which, in the presence of bromide, yields free bromine. Chemically, the reaction is: $\text{KBrO}_3 + 3\text{H}_2\text{SO}_4 + 5\text{KBr} \rightarrow 3\text{Br}_2 + 3\text{H}_2\text{O} + 3\text{K}_2\text{SO}_4$. The method of performing the test with the most useful proportions to employ is:

1. Add .5 cc. of a 2:1 mixture of 20% H_2SO_4 and a saturated solution of KBrO_3 to 3 cc. of urine.

2. Stopper the tube, invert to mix, and allow to stand for 3 minutes.

3. Add $\frac{1}{2}$ cc. of either chloroform or Toluene; restopper the tube; shake; and allow to stand until separation takes place. The separation is usually complete in 2 minutes.

4. A positive test for the presence of bromides is the appearance of an orange to red color in the extractant.

To determine the sensitivity of this urine test, bromides were administered to several patients. Serum levels up to 200 mg.% were obtained. Medication was stopped and bi-weekly serum bromide levels were determined and correlated with daily qualitative urines. The bromide serum level of Patient "A" declined from 195 mg.% to 115 mg.% in 7 days and daily urinary bromides were distinctly positive down through a serum level of 80 mg.%. Although it has been cited that urine concentration parallels that of serum(2), in our hands, urine bromide levels run about one-half that of serum levels. This urine test is sensitive to at least 40 mg.% of bromide in urine, and this end point is further confirmed by serial solutions of bromides.

Theoretically and actually, the sensitivity of the test could be and is improved by using larger amounts of urine. The 3 cc. amount has been selected as certain to detect the presence of bromides in the toxic range. Subsequent to the development of this test, it was brought to our attention that a urine bromide test has been described in the literature for many years, utilizing fuming nitric acid. We found this test, as described, to be completely insensitive to bromide.

The commitment to state hospitals of patients with psychoses due to bromide intoxications remains a present day occurrence. The value of early diagnosis would be the frequent possibility of treatment in the general hospital and the avoidance of needless commitment. We would like to suggest that the urine screening test for bromides described herein would be of assistance in the diagnosis of cases where Bromism is a possibility. It is further suggested that this test could be easily incorporated into the admission urinalysis

in state hospitals in order to determine present incidence and to provide for early treatment.

PROMAZINE AND COMBINED PROMAZINE-MEPROBAMATE TREATMENT OF HOSPITALIZED PSYCHOTIC PATIENTS

GEORGE VLAVIANOS, M.D., AND LUDWIG FINK, M.D.¹

After a 13 month preliminary trial of promazine² in 200 hospitalized mental patients,^{1, 2} a supplementary study,³ which extended the total treatment period to 29 months, was initiated in an additional 100 chronically and severely psychotic men. The diagnoses included: 1. schizophrenia, 2. alcoholic psychosis, 3. psychoneurosis, 4. psychopathic personality, 5. The patients' ages ranged from 24 to 73 years; the duration of illness, 3 to 25 years. In the last 12 months of the study, 69 of the 100 patients were treated with promazine and meprobamate⁴ in combination. All of the 100 had received ataractic compounds for 5 to 18 months, 17 simultaneously with electroshock, 3 with insulin coma and 1 with insulin coma combined with EST.

In refractory cases, promazine was administered in larger than the previously used dosages. Nine extremely noisy, unmanageable, acutely hallucinating patients received maximum doses of 4.5 gm. for 14 to 42 days, and were maintained with 600 to 900 mg. daily. For selected cases in which restlessness, motor hyperactivity, and agitation with depression were predominant, promazine was used in combination with meprobamate. The optimum response usually was obtained with 900 mg. to 1.5 gm. promazine and 1.2 gm. meprobamate daily. For maintenance, daily doses of 600 mg. promazine and 800 mg. meprobamate

generally sufficed. For the catatonic and negativistic, a "break-through" trial was conducted with promazine alone. If there was no response, EST was administered, after which medication with promazine was resumed.

Psychomotor excitement and destructiveness generally were controlled with the higher doses of promazine. In selected chronic cases joint administration of lower doses of promazine with meprobamate, individually adjusted, produced the same effect as higher doses of promazine used alone, and aided liberalization of the ward program. Need of EST and coma therapy was reduced, and indications for lobotomy minimized. Eighty-three (nearly 28%) of the overall total of 300 have been released. Of these 17 (20%) have returned; alcoholism necessitated readmission in 10. The mental disorder was not intensified by the medication, nor were there any signs of habituation.

Drowsiness and dysarthria developed in 2 of the 9 who received high doses of promazine, but subsided in a maximum of 15 days after reduction of the dose. Grand mal seizures occurred in 3, who had received daily doses of 900 mg., 2.4 and 3 gm. promazine respectively. Discontinuance for 10 days and resumption at 300 mg. per day induced no further seizures in 2. In the third patient one additional seizure occurred after 13 days. Phenobarbital, 1½ grains twice daily, was added to the regimen for 2 months after which promazine alone, in daily doses of 300 mg., has produced no recurrence in the ensuing 8 months. Monthly routine laboratory studies demonstrated high alkaline phosphatase levels in 3 patients who received daily

⁴ Meprobamate is available as Equanil from Wyeth Laboratories.

of 600 to 900 mg. promazine alone. The findings became normal after reduction of the dose to 300 mg. daily. In addition, clinical improvement permitted continuance of treatment.

Orthostatic dizziness or fainting occurred in 3 who received promazine alone, and in 4 who received both compounds, but did not contraindicate medication. A mild rash and itching developed in 12 of the 69 (17%) who received the

combination, had no relation to dosage or duration of treatment, and subsided on discontinuance. This was considered an expression of individual sensitivity, probably to meprobamate.

DRUG USE-RATE IN A STATE HOSPITAL

J. R. WHITTIER, C. D. KORENYI, O. DIAMOND, P. J. TOMLINSON, AND
H. A. LABURT¹

In 1954 the medications chlorpromazine and reserpine were made available to hospitals for the mentally ill in the United States. Additional drugs have appeared since then, and their overall effectiveness has considerably modified psychiatric treatment.

Whether a drug once introduced continues to be prescribed might be determined by the ratio of therapeutic effectiveness to the incidence of undesirable side effect, provided the elements of this ratio were defined. Additional determining factors include at least 1. The drug's availability from the hospital pharmacy, 2. Pressure by pharmaceutical representatives to initiate and continue use, 3. The kind and volume of information available concerning new drugs, 4. Attitudes to drug therapy of physicians responsible for patients, and 5. The policy of the hospital administration to drug use.

This article provides graphic records of the use-rates of tranquilizing and stimulant drugs in a large state hospital.

MATERIAL AND METHODS

In the New York State Department of Mental Hygiene a special form was revised in February 1955 (Form 41-DMH) to permit reporting of total patients receiving chlorpromazine and reserpine, and male and female sub-totals. These reports were added to those previously submitted de-

scribing use-rates of convulsive and insulin therapy.

In January 1957 this form was again revised to include additional tranquilizing drugs, other special therapies, special somatic therapy of the aged, and psychotherapy.

The hospital report is consolidated monthly from reports of the physicians responsible for the wards. The reports of special therapies were available for the 4 year period from January 1954 to December 1958 inclusive. Data from each of 9 tranquilizing drugs or combinations and 3 stimulant drugs were plotted graphically (Figure 1). Only drugs reported as being prescribed to 10 or more patients were included in the study. Hormones, vitamins, and drugs in experimental status were not included. At the end of 1958, the total hospital population was 6,325 (2,621 males and 3,704 females).

RESULTS

It will be noted that a use-rate listing of drugs by descending order is: 1. Chlorpromazine, 2. Promazine ("Sparine" Wyeth), 3. Reserpine, 4. Prochlorperazine ("Compazine" SKF), 5. Meprobamate ("Equanil" Wyeth—"Miltown" Wallace), 6. Triflupromazine ("Vesprin" Squibb), 7. Mepazine ("Pacatal" Warner-Chilcott). Chlorpromazine demonstrates by far the greatest use-rate, approximately 4 times that of its nearest competitor, promazine.

¹ Creedmoor State Hosp., Queens Village 27, N. Y.

FIGURE 1
NUMBER OF PATIENTS RECEIVING EACH DRUG MONTHLY (ORDINATE) DURING THE FOUR YEAR PERIOD STUDIED (ABSCISSA). NOTE THAT ORDINATES DIFFER.

Drugs manifesting continuing steady growth in use-rate are as follows, in rank order: reserpine, prochlorperazine, meprobamate, triflupromazine, benzedrine. Drugs presently stabilized in use-rate after steady growth are as follows, in rank order: chlorpromazine, promazine. Drugs manifesting growth and decline are: methylphenidate, mepazine (male service).

The fluctuation in use of mepazine on the male service was apparently related to the introduction of triflupromazine, which competed effectively for use on the available population of this service.

Notable use-rate phenomena include the rapid rise for triflupromazine, the relatively large numbers of females receiving prochlorperazine, and the passage of reserpine by promazine in May of 1957. The brief appearance of iproniazid was determined by a departmental decision temporarily to suspend use until toxicity was better defined.

A tendency for use-rate by sex to follow hospital population sex distribution is apparent. Use-rate total for female patients exceeds that for male patients for all drugs except reserpine, triflupromazine, mepazine and benzedrine.

Finally, there is an increasing trend to the use of new drugs for more patients, manifested by the irregular increase in the

initiating of new drugs on the services: 2 in 1955, 1 in 1956 and 4 each in the years 1957 and 1958. Combinations of 2 or more drugs began to appear in 1958 (2 instances). By the end of the observation period, 61% of the total hospital population, (21% of the male, and 40% of the female populations) were receiving one or more of the drugs. Of the total, male, and female patients on drugs, 34%, 11%, and 23% respectively were receiving chlorpromazine.

SUMMARY

Use-rates for 9 tranquilizing and 3 stimulant drugs or drug-combinations were recorded in a state hospital population over a 4 year period, ending December 31, 1958. Data were plotted graphically, and use-rates were observed in descending order for chlorpromazine, promazine, reserpine, prochlorpromazine, meprobamate, triflupromazine, mepazine, mepazine plus chlorpromazine, reserpine plus chlorpromazine, benzedrine, methylphenidate, and iproniazid.

By the end of the observation period, 61% of the total hospital population, (21% of the male, and 40% of the female populations) were receiving one or more of the drugs. Of the total, male, and female populations on drugs, 34%, 11%, and 23% respectively were receiving chlorpromazine.

ADMINISTRATIVE NOTES

MENTALLY DISTURBED CHILDREN ON WARDS WITH ADULT MENTAL PATIENTS

OTT B. McATEE, M.D., AND GEORGE A. ZIRKLE, Ph.D.¹

Hospital administrators and the public in general have been led to feel that it would be like putting a "lamb in a lion's cage" to admit a mentally ill child to an adult ward of mental patients. Is this stereotyped view correct? It is the contention of the authors that it is not. Furthermore, just the opposite may be true. This is not an idle opinion, but derives from a detailed research investigation of two children who were patients at this Hospital. One was a 12-year-old boy and the other an 11-year-old girl. After an initial period of hesitation, these children adjusted rapidly to the adults on their ward. Their recovery was not hampered by the adults, nor were they abused. Instead, they became the objects of much "tender, loving care." Some adults even vied with each other to do things for them. This was especially true of those who had children of their own. Most of these quickly assumed the "father" or "mother" role. And surely this should not be surprising; for the common human situation is for the different ages to live together in families.

A 3-fold plan was used in evaluating the success of the "family" situation on the ward. First, the number of social contacts of each child with others on the ward were counted over a 2-day period. The same was done for 2 adult patients in each ward who were matched with the children as closely as possible, except for age. Results showed decidedly more child-adult contacts than adult-adult contacts. The same was found to be true when the children were placed on visiting wards for a day. Secondly, a sociometric nominating procedure revealed the children to be among the most popular on their wards.

The third procedure was to poll the opinions of nurses and attendants on the

wards in question. Some disapproved the arrangement at the start, and continued to do so. They noted that the children made some patients nervous, and others homesick for their own children. They predicted the children would be spoiled by so much attention. However, other nurses and attendants changed from skepticism to acceptance, and in some cases to enthusiasm over the therapeutic possibilities of the family ward situation for adults and children alike. They remarked on the warm social relationships stimulated by the children. And they expressed approval for the decline in egocentric preoccupation in some patients who cooperated with each other to do things for the children. The ward routine was not disrupted, but was made more lively by the presence of the children. No sex interest in the children was noted, but general interest in their activities and loving care for them was frequently observed. Male patients tended to abstain from using profanity or smutty talk before the boy.

There is no wish to imply that children and adults should be mixed together indiscriminately. Age segregation will no doubt continue to be needed for most mental patients. The view that it must be maintained for *all*, however, was not supported by these findings. Stereotyped fears at this point need to be discarded. In the light of the research results, it is the authors' opinion that an occasional child placed on an adult ward will find there a suitable treatment environment and, moreover, that the presence of the child will enhance the therapeutic milieu of the adults. In other words, it is contended that the family or mixed-age ward constitutes a distinctive form of treatment, and that it deserves a serious place along with other environmental treatment measures in hospital management. For carefully selected children and adults it has real value.

COMMENT

PERSONALITY AND PERFORMANCE

ELI GINZBERG¹

After eight years of research, during which it had the full cooperation of the Army and the Veterans Administration, the Conservation of Human Resources Project has recently published *The Ineffective Soldier: Lessons for Management and the Nation* in three volumes entitled "The Lost Division," "Breakdown and Recovery," and "Patterns of Performance" (Columbia University Press, \$6.00 each).

At an early stage of the investigation the Conservation staff was fortunate to elicit the cooperation of 35 psychiatrists who had held senior positions in the Armed Services during World War II. An analysis of their communications was published in 1953 under the title *Psychiatry and Military Manpower Policy: A Reappraisal of the Experience in World War II*, and many of the leads which they provided were most helpful.

Even if one selects only those findings that are likely to be of greatest interest to psychiatrists, it is not easy to summarize about 900 pages of text, with 150 key tables which present data almost all of which have never been published before. The most useful procedure will be to set out the broader theoretical findings and to weave a minimum number of facts around them.

Perhaps one of the most important findings of the entire investigation is the widespread effort to predict performance solely, or even primarily, in terms of "emotional stability." The ability of a man to get a job, to marry and support his dependents and to stay out of trouble with the law—minimum criteria for socially acceptable performance—depend primarily on his physical and intellectual capacities and his motivation. While emotional factors are important for understanding how a man feels, they are likely to keep him from

performing acceptably only if the disturbance is a serious one.

The proper study of performance must go beyond the individual and include a consideration of how the policies of the organization for which he works and the pressures and supports in the larger environment affect his performance. In *Breakdown and Recovery* the Conservation staff presents about 80 detailed case histories selected specifically to illuminate the multiple factors in performance—individual, managerial, environmental.

The foregoing helps to explain why it was that although 1.75 million men were rejected for mental or emotional reasons in World War II, another 750,000 had to be prematurely separated for the same causes. Aside from serious limitations in screening procedures the basic theory of psychiatric selection was faulty. Only about 170,000—or approximately 1 in every 5 men who was prematurely separated—had clear indications in their records of ineffectiveness, which, had they been noted, would have led to their being rejected at induction. Better screening would have identified more potential failures, but the important point to stress is that for the country as a whole, higher rejection rates were found *not* to be associated with lower separation rates. With 1 out of every 7 young men in the country being rejected or prematurely separated, raising the screening criteria would have been no solution. If that had been done, the Armed Forces would not have been able to meet their manpower requirements.

The single most useful criterion for assessing a man's potential performance is his educational background. Those with only a few years of grade school had an ineffectiveness rate in the Army four times greater than the high school or college men. A surprising finding was that men who had been divorced at the time of their induction and those who had re-

¹ Director, Conservation of Human Resources Project, Columbia University, New York 27, N. Y.

remained single during the decade after their separation had a five times greater rate of ineffectiveness in their life performance patterns than did those who had married and stayed married. Apparently, marital difficulties frequently reflect fundamental personality difficulties that affect all aspects of a person's performance.

Another interesting and important finding that warns against the indiscriminate use of clinical categories for the purpose of predicting performance is the record of soldiers who suffered from a psychosis. We were impressed to find many men who were unquestionably psychotic who managed for considerable periods to perform satisfactorily. Moreover, approximately half of all the men discharged for psychosis readjusted after the war.

The record of the entire group of half a million soldiers who were discharged for ineffectiveness showed that approximately 7 out of 10 were able to make a satisfactory readjustment to civilian life, some quickly, some more slowly. While we were able to identify many different factors as contributing to the successful readjustments of these veterans—discharge from the Army, family supports, disability compensation, medical care—by far the most important appeared to be the high level of employment. The ability of a man to shift around until he found a job to his liking and the willingness of employers to make adjustments to meet his special needs, particularly during his first months at work, proved a boon. A job means purpose, companionship, sense of accomplishment, income, status, and the ability to discharge one's obligations. A job is the precondition for adjustment; unemployment is the greatest individual and social scourge.

In *Patterns of Performance* the staff had an opportunity to evaluate a man's performance over several decades—before, during, and after military service. This approach helped to illuminate the extent to which men's performance tends to be more or less stable over longer periods and further to identify the strategic factors responsible for stability or fluctuation in their life performance patterns. Somewhat over half of the entire group show an

"adjusted" life performance pattern. About 20% had a "vulnerable" pattern—they performed satisfactorily in civilian life but could not meet the demands of the Army. About 10% had a broken pattern—satisfactory performance record up to breakdown in the Army but no recovery. The remainder, about 17%, had a consistently poor record—before, during, and after military service.

The investigation helps to correct some widespread misconceptions. For instance, only 1 out of every 5 men who became ineffective ever saw combat; only 2 out of every 5 ever got overseas. Even more surprising is the finding that the wounded veteran who was discharged for psychiatric reasons had the highest recovery rate, doubtlessly reflecting better selection for combat units. While Negroes generally had an ineffectiveness rate twice that of whites, no significant difference is found when they are matched with whites as to education. In every regard the farm group showed up more poorly than the urban group: it had higher rates of rejection, higher breakdown rates in the Army, and lower recovery rates after the war. Once again, the explanation must be found primarily in differences in developmental opportunities, particularly educational opportunities.

No support could be found for the belief that liberal disability compensation impedes recovery. In general, the wide range of benefits made available by the Veterans Administration was judiciously administered and definitely helped to speed the recovery of many veterans.

The subtitle of the over-all study—"Lessons for Management and the Nation"—suggests the basic concern of the Conservation staff with questions of policy. For better or worse, psychiatrists became very deeply involved during World War II in policy considerations affecting the whole gamut of military personnel practices and procedures. Increasingly, their concerns continue to take them outside the mental hospital and their offices. As their focus shifts from the individual patient to large groups, it is hoped that the three volumes on *The Ineffective Soldier* can help them to broaden their understanding of the

complex nature of performance. For in working with him, it says the psychiatrist, we need to bring our approach beyond the domain of psychodynamics to take account of the ways in which the actions of management and the forces in the larger environment contribute to or detract from effective performance.

HABIT

Habit is thus the enormous fly-wheel of society, its most precious conservative agent. It alone is what keeps us all within the bounds of ordinance. . . . It alone prevents the hardest and most repulsive walks of life from being deserted by those brought up to tread therein. It keeps the fisherman and the deck-hand at sea through the winter, it holds the miner in his darkness, and nails the countryman to his log-cabin and his lonely farm through all the months of snow. . . . It dooms us all to fight out the battle of life upon the lines of our nurture or our early choice, and to make the best of a pursuit that disagrees, because there is no other for which we are fitted, and it is too late to begin again. It keeps the different social strata from mixing. . . . It is well for the world that in most of us, by the age of thirty, the character has set like plaster, and will never soften again.

—WILLIAM JAMES

CORRESPONDENCE

CONCERNING THE ORIGIN OF THE TERMS GROUP THERAPY AND GROUP PSYCHOTHERAPY

Editor, THE AMERICAN JOURNAL OF PSYCHIATRY:

SIR: In a review of Corsini's *Methods of Group Psychotherapy*, in the March 1959 issue of this Journal, p. 840, Mr. Illing says: "Moreno claims for himself the first coining of the term 'group psychotherapy' (1932), without, however, substantiating his claim, although he cites many 'witnesses' for his testimony, such as William Alanson White, Wierzbicki, Overholser, Pierre Renouvier, S. H. Boulkes."

Here follows the record in my own publications: *Application of the Group Method to Classification*, Congressional Library, No. 42-26884, Publisher: National Committee on Prisons, New York, 1931-32, a chapter "Concerning Group Therapy," p. 60-61; "Illustration of Group Therapeutics," p. 74-76; "Group Therapy in an Institution of the Insane," p. 77-79, "Definition of Group Therapy," p. 103.

The *Group Method* monograph was the topic of a Round Table at the annual meeting of the APA, May 31, 1932, Moderator: William A. White. At this meeting the term "group psychotherapy" was first given currency by the author.

The term "group psychotherapy" is recorded in my book *Who Shall Survive?* with a Foreword by Wm. White, Nervous and Mental Disease Publishing Co., Washington, D. C., First edition, 1934, Congression-

al Library No. 34-18502; see p. 437, 429, referring to chapter "Group Psychotherapy," and the definition, p. 301, "Group therapy treats not only the individual who is the focus of attention because of maladjustment, but the whole group of individuals who are interrelated."

Group psychotherapy owed its emergence to sociometry and small group dynamics which was expounded by the author between 1931 and 34; he formulated group therapy as a scientific methodology with the help of Drs. White, Whitin, Branham and Jennings. There have been forerunners of pre-scientific group methods in the U. S. A. and Europe before 1931. The most important influence came from Vienna since 1909. Many of these methods (psychodrama, 1911, interaction methods, 1913, psychodrama combined with group therapy, 1923) have been launched by this author and described in his German books.

It is farfetched to trace the origins of group psychotherapy to European sociologists. One could equally quote American sociologists. Every new idea has forerunners but the moment of emergence of the scientific group psychotherapy movement into scientific history, its *kairos*, was the year 1932, within the fold of the American Psychiatric Association.

J. L. Moreno, M. D.,
Beacon, N. Y.

REPLY TO THE FOREGOING

Editor, THE AMERICAN JOURNAL OF PSYCHIATRY:

SIR: In stating: "Moreno claims for himself the first coining of the term 'group psychotherapy,' without, however, substantiating his claim, although he cites many 'witnesses,' such as . . .," in my review I quoted Dr. Moreno as having quoted his witnesses. I have not stated that Dr. Moreno was not the first person to use

the term "group psychotherapy"; I have stated that he *claimed* to be the first one.

Dr. Moreno refers to *Application of the Group Method to Classification*, published in 1932, and in 1957, entitled: *The First Book Moreno on Group Psychotherapy*. Moreno 25th Anniversary 1932-1957 Moreno. The heading of page 60 reads: "Concerning Group Therapy." However, the text does not mention the word "therapy" once.

The Glossary contains a definition of "group therapy: A Method of psychotherapy which combines the technique of assignment with the technique of spontaneous treatment." I am still at a loss to understand why group therapy has to be explained since it does not occur elsewhere in the text.

On the other hand, I received assurances from individuals that they, too, laid claim to having invented the term "group psychotherapy." Dr. Rudolf Dreikurs showed me his manuscript containing the protocols of his group psychotherapy sessions in his private practice in Vienna in 1927. According to Dr. Corsini (having published one of the most comprehensive bibliographies—some 1,700 titles!—in *Group Psychotherapy*), the first writer having used the term "group therapy" in the title of a publication was L. C. Marsh in 1935. Dr. George R.

Bach and I have shown in *Die Zeitschrift fuer Psycho-Somatische Medizin* (1956) that the French neurologists, J. Camus and P. Pagniez, used the term group therapy in their paper, "Isolation and Psychotherapy," published by Alcan in Paris in 1904! S. R. Slavson claims of having used the term in 1935 at the Jewish Board of Guardians in New York.

It is obvious that Dr. Moreno has played a large and continuing part in group psychotherapy of the particular variety in which he is interested. I would like to make it clear that any statements about the origin of the phrase "group psychotherapy" is intended only to define its origin historically and not to detract from Dr. Moreno's part in this history.

Hans A. Illing, Ph.D.,
Los Angeles, Calif.

MALADIE DES TICS IN CHILDREN

Editor, THE AMERICAN JOURNAL OF PSYCHIATRY:

SIR: I found the article, "A Clinical Study of Gilles de la Tourette's Disease (*Maladie des Tics*) in Children," by Eisenberg *et al.* (Am. J. Psychiat., 115, No. 8, Feb. 1959) very interesting. I would like to make several points about the article as follows.

The authors make the following statement: "Its rarity is attested to by the infrequency of case reports." This is not necessarily so. I have personally worked with 2 such cases in the last 4 years. The first case was seen in 1954; I am currently working with the second case which was first seen one year ago. It would be equally wrong to conclude that, because I have seen 2 cases in 4 years, therefore *maladie des tics* is commonly seen. I do not believe there is necessarily a correlation between the frequency with which this type of case occurs and the number of cases reported in the literature. For example, Ferenczi, whose work on tics(1) is widely quoted, depended on the work of Meige and Feindel(2) for much of his case material. Wilson, who is quoted as saying that the prognosis in *maladie des tics* is "sinister,"

also adds that at the time of writing he had not seen a case in years.

The authors state that "The etiology of Gilles de la Tourette's disease remains as obscure as it was in his time. . . ." They also imply that therapy so far has not been successful except where one could modify the environment. They unequivocally dismiss pharmacologic therapy as ineffective in their cases.

It is difficult to generalize on the basis of 2 cases but my experience differs from theirs in relation to etiology and therapy.

The first case was that of a 14 year old girl first seen 5 years ago. The tics, behavior and learning difficulties started after a severe case of measles when the child was 8. The neurological examination only noted the characteristic tics; the EEG was difficult to evaluate because of the movements. The psychological examination was of significance because the results as compared to a previous psychological record pointed to some deterioration. The psychological profile also showed indications of organic involvement. My impression was that this was a post-encephalitis case and would not respond to psychotherapy. However, because the girl did not respond to medication of various kinds, I agreed to refer her to a colleague who believed he might help

NEWS AND NOTES

KAREN HORNEY CLINIC FELLOWSHIP OF THE AMERICAN INSTITUTE FOR PSYCHOANALYSIS.—A \$5,000 fellowship is available to psychiatrists applying for the full course of training in the American Institute for Psychoanalysis. The recipient will be granted \$2,500 per annum during the second and third years.

Candidates must be graduates of an A.M.A. accredited medical school and have completed a one year general internship and two years psychiatric residency in hospitals approved by the A.M.A.

For further information write to the Registrar, Miss Janet Frey, American Institute of Psychoanalysis, 220 W. 98th St., New York 25, N. Y.

BIBLIOGRAPHY OF PSYCHOPHARMACOLOGY.—The National Library of Medicine of the Public Health Service has issued a 258 page bibliography entitled *Psychopharmacology*, compiled by Anne E. Caldwell, M.D. It contains references to approximately 2,500 articles, published between Jan. 1952 and Dec. 1956, concerned with the effect of psychopharmacologic agents on the psychologic, behavioral and encephalographic reactions of normal subjects, patients and laboratory animals.

The book is divided into 4 sections: 1. Drug Index, which lists the chemical, trade and generic names of drugs, drug groups and trade names of drug combinations with their composition; 2. Subject List of Drugs, and alphabetical listing with references; 3. Ancillary Subject List of Special Conditions and 4. An alphabetical Author List.

The book may be obtained from the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Price, \$1.50.

DR. NOYES RETIRES.—Dr. John E. Davis, Commissioner of Mental Health for the State of Pennsylvania, sends the information that informal ceremonies honoring Dr. Arthur P. Noyes, former President of

the APA, on the occasion of his retirement as superintendent of Norristown State Hospital, were held on Thursday, June 11, 1959, at the Hospital.

Since 1916 Dr. Noyes has held important posts in several hospitals in the east including Boston Psychopathic, St. Elizabeths and the Rhode Island State Hospital for Mental Diseases. He was superintendent at the latter institute for seven years when he was called to the superintendency of the Norristown State Hospital in 1936. He is the author of *Modern Clinical Psychiatry* and co-author of *Textbook of Psychiatric Nursing*, each in its fifth edition.

WORLD REHABILITATION FUND, INC.—The creation of the Frank H. Rowe Memorial Fellowship in Rehabilitation for post-graduate training in physical medicine and rehabilitation in the United States for a physician from Australia was announced, June 1, 1959, simultaneously in Melbourne and New York. The fellowship is being given by the World Rehabilitation Fund, Inc. in cooperation with the Australian Advisory Council for the Physically Handicapped, the International Society for the Welfare of Cripples, and the Smith Kline and French Foundation. The Fellowship was created to honor the late Frank H. Rowe, C.B.E., Director-General of Social Services, Commonwealth of Australia, 1949-1958, for his contribution to the development of rehabilitation services for the physically handicapped internationally.

The Fellowship is for a minimum of one year and is subject to renewal. Training under the Frank H. Rowe Memorial Fellowship will be given at the Institute of Physical Medicine and Rehabilitation, New York University-Bellevue Medical Center, N. Y. C.

Currently there are 71 trainees (57 physicians and 14 non-physicians) from 35 different nations receiving long-term advanced training in the United States under the auspices of the fund.

Address: World Rehabilitation Fund, Inc., 400 East 34th St., New York 16, N. Y. President: Dr. Howard A. Rusk.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY, INC.—In February, 1959, the American Board was authorized to undertake sub-specialty certification in Child Psychiatry. The following physicians, all Diplomates in General Psychiatry of the American Board of Psychiatry and Neurology, have been certified in the sub-specialty of Child Psychiatry:

Frederick H. Allen, M.D., Philadelphia 29, Pa.

Frank J. Curran, M.D., New York 28, N. Y.

Othilda Krug, M.D., Cincinnati 29, Ohio.

William Siddon Langford, M.D., New York 32, N. Y.

Hyman S. Lippman, M.D., St. Paul 4, Minn.

Joseph Franklin Robinson, M.D., Wilkes-Barre, Pa.

THE ACADEMY OF PSYCHOSOMATIC MEDICINE.—The sixth annual meeting of The Academy will be held October 15-17, 1959 at the Sheraton-Cleveland Hotel in Cleveland, Ohio. The meeting will be directed to the needs of nonpsychiatric physicians. Everyday office management of psychosomatic problems will be dealt with in formal papers, symposia, panel discussions, and small study groups.

The meeting will be open to physicians, psychologists, social workers and nurses. Information may be obtained from Dr. Bertram B. Moss, Suite 1035, 55 East Washington St., Chicago 2, Ill.

HISTORY OF THE BEHAVIORAL SCIENCES NEWSLETTER.—The history of the development of the behavioral sciences is a relatively new research area, to which numerous scattered workers have been attracted. As a medium of communication and information a newsletter is to be established in the interests of anthropologists, psychiatrists, psychologists, and any others working in this area. It will provide a means of requesting specialized information and bibliographical material; and it

will list new books and cooperative surveys and developments pertinent to this field.

The specific purpose of the first issue is to contact those interested in the behavioral sciences, to solicit their suggestions and to obtain names and addresses from them of others interested in this area.

For further information write to Dr. Eric T. Carlson, Payne Whitney Psychiatric Clinic, New York Hospital, 525 East 68th St., New York 21, N. Y.

EDUCATION OF PSYCHIATRIC AIDES.—The National League for Nursing has published a 27-page booklet entitled *Suggestions for Experimentation in the Education of Psychiatric Aides*, which points out the importance of preservice training of psychiatric aides and makes suggestions as to objectives, curriculum and evaluation of the students.

The pamphlet is available from The National League for Nursing, 10 Columbus Circle, New York 19, N. Y. Price, \$1.00.

EASTERN PSYCHIATRIC RESEARCH ASSOC., INC.—The Association will hold its fourth annual meeting October 23-24, 1959, at the Waldorf-Astoria Hotel, N. Y. C. Papers will be given under the general headings of Chemical and Behavioral Aspects of Psychoses; and a Symposium on the Genetics of Disordered Behavior. There will also be a panel discussion on Neuropsychiatric Aspects of Space and Depth Medicine.

For further information write to David J. Impastato, M.D., Eastern Psychiatric Research Assoc., Inc., 40 Fifth Ave., New York, N. Y.

NEW YORK STATE NARCOTIC ADDICTION RESEARCH.—At Manhattan State Hospital is now located the first research unit in narcotic addiction in New York State. It will contain 55 beds for inpatients and ample provision also for outpatient care.

The work of the center will be integrated with the new program of treatment and clinical research conducted by the city of New York.

MID-CONTINENT PSYCHIATRIC ASSOCIATION.—The annual meeting of the Mid-

Continent Psychiatric Association will be held September 18-20, 1959, at the Holiday Inn Hotel, St. Louis County, Mo. President James N. Haddock, St. Louis, will preside and the incoming president is Dr. Louis Cohen, Little Rock, Ark. Twelve scientific papers will be presented. Out-of-town speakers will include Dr. Adolph Sahs, Iowa City; Dr. Joseph B. Parker, Jr., Lexington, Ky.; Dr. Manfred Guttmacher, Baltimore; Dr. John O'Hearne, Kansas City; Dr. Charles Shagass, Iowa City; and Dr. Herbert Modlin, Topeka.

For further information write James N. Haddock, M.D., President, 950 Francis Place, Clayton 5, Mo.

NATIONAL ASSOCIATION FOR MENTAL HEALTH.—In its Annual Report, issued June 8, 1959, the N.A.M.H. stated that the number of resident patients in state and county mental hospitals stood at 545,000 on December 31, 1958, compared to 548,000 at the end of 1957, a reduction of approximately one-half of one percent. Admissions in 1958 rose sharply, from 195,000 in 1957 to 210,000 in 1958, a rise of about 8%.

The report also mentioned that federal government appropriations for research, training and community services rose substantially in 1958. Congress appropriated \$52,000,000 for the budget of the National Institute of Mental Health, compared with \$37,000,000 in 1957.

NORTH PACIFIC DISTRICT BRANCH, APA.—The third divisional meeting of Area 5 will be held in Seattle, Wash., September 24-27 as a joint meeting with the West Coast Psychoanalytic Society. Members not living in the 13 western states may make hotel reservations by writing Marcus R. Stuen, M.D., 1206 South 11th St., Building 17, Tacoma 5, Wash.

The joint meeting will be preceded by meetings of the Western Group Psychotherapy Society, September 21-23 and two sponsored by the Western Interstate Commission on Higher Education, Directors of Nursing Services and Directors of Education at Lake Wilderness, September 21-23 and Mental Hospital Superintendents the afternoon and evening of September 23.

CAMBRIDGE UNIVERSITY SYMPOSIUM ON DEPRESSION.—This symposium will be held at Cambridge from September 22 to 26, 1959, inclusive. It will consist of lectures and discussions on the following 4 aspects of the subject: clinical, neuropharmacological, psychological, therapeutic, one of which will be discussed each day. The Proceedings of the symposium will be in English and will be published by the Cambridge University Press.

Accommodation and board will be provided in Clare College, and inclusive of gratuities will be £10 10s. The fee for the full course is £6 6s. 0d.; part-time, £1 11s. 6d. per day.

The symposium will be introduced by Prof. Aubrey Lewis, Maudsley Hospital, London; the lecturers will include Prof. Leucio Bini, Rome; Prof. Cazzullo, Milan; Dr. E. Beresford Davies, Cambridge; Dr. Russell Davis, Cambridge; Dr. Deniker, Paris; Dr. Feldberg, London; Dr. James Flind, London; Dr. Hoffer, London; Prof. Mayer-Gross, Birmingham; Prof. Rothlin, Basle; Dr. Sargant, London; Prof. Jackson Smith, Nebraska; Prof. Zamgwill, Cambridge.

DIRECTORS OF PRIVATE NON-PROFIT MENTAL INSTITUTIONS MEET.—In 1844 Dr. Thomas Kirkbride and 12 other heads of hospitals held a meeting on the grounds of the Pennsylvania Hospital in Philadelphia, at what was then a rather new hospital at 44th and Market Streets.

Through the years the directors of the private non-profit mental institutions on the Atlantic coast have met from time to time and discussed their mutual problems. This practice has continued to the present time. On June 12, 1959, at the invitation of Dr. Lauren H. Smith, the Physician-in-Chief and Administrator of The Institute of the Pennsylvania Hospital, 8 directors of these same institutions visited the new Institute of the Pennsylvania Hospital which was opened on January 28, 1959, simultaneously with the closing of the famous old 44th Street Department. The directors spent some time in going through the colorful new building which is furnished in modern furnishings and air conditioned throughout. They then adjourned to a luncheon meet-

ing where many problems were reviewed.

Of special interest were studies furnished by each director of the ratio of the nursing personnel to the average census of patients, emphasizing the interrelationship of the nursing education division to the relative costs of such in the hospital treatment program. The group felt that it might be advisable, if possible, to undertake a short

research study as to the cost of nursing education in private non-profit mental hospitals, and how much it added to the financial burden carried by families, even though it was obvious that the presence of such nursing schools in these psychiatric hospitals maintain a very desirable nurse patient ratio that added much to their treatment program.

OFFICIAL REPORTS

HOSPITALS APPROVED AND CONDITIONALLY APPROVED BY THE CENTRAL INSPECTION BOARD

As of May 15, 1959, the following hospitals have been added to the list of the Central Inspection Board published in the August 1958 issue of this Journal, page 173:

Approved: Compton Sanitarium, Compton, Cal.; Hall-Brooke Sanitarium, Green Farms, Conn.; Anclote Manor, Tarpon Springs, Fla.; Brawner's Sanitarium, Smyrna, Ga.; Falkirk Hospital, Central Valley, N. Y.; Four Winds, Katonah, N. Y., Appalachian Hall, Asheville, N. C.; St. Albans Psychiatric Hospital, Radford, Va.; Tucker Hospital, Inc., Richmond, Va.; Westbrook Sanatorium, Richmond, Va.; and Clinique Roy-Rousseau, Mastai, P. Q., Canada (all private hospitals).

Conditionally Approved: Clearview Hospital, Evansville, Ind. (private hospital).

THE AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY, INC.

The following candidates were certified by this Board after examination in New Orleans, La., March 16-17, 1959.

PSYCHIATRY

- Abrams, Arnold Louis, 270 Commonwealth Ave., Boston 15, Mass.
 Agnew, Paul Comstock, 679 North Michigan Ave., Chicago 11, Ill.
 Alvarez, Flavio E., Clausells Bldg., Ponce, Puerto Rico.
 Arenowitz, Albert H., 5058 LaCrosse La., Madison, Wis.
 Baker, Cecil G., Box 76, Yankton, S. D.
 Bergsma, Stuart, 1942 Sherman St., S.E., Grand Rapids 6, Mich.
 Bernstein, Joseph I., 26 Mulberry St., Springfield, Mass.
 Bonsredt, Theodor, 256 Summit St., Marion, Ohio.
 Bronstein, Milton H., 9735 Wilshire Blvd., Beverly Hills, Calif.
 Burke, Henry L., 725 North University Ave., Ann Arbor, Mich.
 Cain, Arthur James, 1075 Pleasant St., Belmont 79, Mass.
 Calobrisi, Arcangelo, 110 East 36th St., New York 16, N. Y.
 Carleton, John Lowndes, Medical Arts Bldg., 1421 Chapala St., Santa Barbara, Calif.
 Carlin, James Floyd, New Jersey State Hosp. at Ancora, P. O. Hammondton, N. J.
 Carson, James E., Brookville Medical Bldg., 6779 Memphis Ave., Brooklyn 9, Ohio.
 Castellnuovo-Tedesco, Pietro, 857 Beacon St., Boston, Mass.
 Click, Paul Robert, 127 North Madison Ave., Pasadena, Calif.
 Cohen, Sanford Irwin, Dept. of Psychiatry, Duke University School of Medicine, Durham, N. C.
 Conkling, Frederic Everett, III, Jackson Memorial Hosp., Miami 36, Fla.
 Cray, Gordon Cameron, 850 Middlefield Rd., Palo Alto, Calif.
 Decker, William A., 1145 Oakland Dr., Kalamazoo, Mich.
 DeMyer, Marian K. H., LaRue D. Carter Memorial Hosp., 1315 West 10th St., Indianapolis 7, Ind.
 De Witt, Horace Daniel, 8 East 96th St., New York 28, N. Y.
 Dominguez, Luis, 31 West 86th St., New York 24, N. Y.
 Dugan, Thomas M., 417 Lincoln St., Johnstown, Pa.
 Ferriz, Jorge, 12 West 96th St., New York 25, N. Y.
 Finney, Joseph Claude Jeans, 207 West Washington St., Urbana, Ill.
 Fisher, Saul H., 124 East 65th St., New York 21, N. Y.
 Fitz Gerald, Joseph A., 1315 West Tenth St., Indianapolis 7, Ind.
 Frank, Alan, Student Health Service, University of Colorado, Boulder, Colo.
 Fuller, David Henry, Jr., State Hosp., Raleigh, N. C.
 Gadpaille, Warren J., 2465 South Downing St., Denver 10, Colo.
 Ginsberg, James P., 612 North Michigan Ave., Chicago 11, Ill.
 Golloway, Glenn G., 26 Brooks Bldg., 201 East Liberty, Ann Arbor, Mich.
 Gray, Helen Marie, 206 East Chestnut St., Louisville 2, Ky.
 Green, Joseph Martin, Kansas Treatment Center for Children, Third and Oakley, Topeka, Kan.
 Gregory, T. Richard, Camelback Professional Bldg., 5051 North 34th St., Phoenix, Ariz.
 Hanni, John William, 40 South Clay St., Hinsdale, Ill.
 Hastings, Philip Ross, VA Hosp., Canandaigua, N. Y.
 Henker, Fred O., III, Dept. of Psychiatry, University of Arkansas Medical Center, Little Rock, Ark.
 Hill, Robert C., 5632 Woodmont Ave., Pittsburgh 17, Pa.
 Hopgood, Winthrop C., 427 North Camden Dr., Beverly Hills, Calif.
 Horenstein, Simon, 360 North Bedford Dr., Beverly Hills, Calif.

Hayster, Howard K., Medical Clinic Bldg., State Hospital, Sacramento, Ca.
Lacey, Peter L., 100 Sutton Pl., South New York 1, N. Y.
Lewin, William, University of Minnesota Hospital, Minneapolis 14, Minn.
Lindner, Gerald, Henry, VA Hosp., 54th St. and 48th Ave., New York, Minneapolis 17, Minn.
Lips, Warren, 1001 North Madison Ave., Pasadena, Calif.
Kaplan, Eugene Herbert, 15 Canterbury Rd., Great Neck, N. Y.
Kaye, Harvey Earle, 66 East 80th St., New York 21, N. Y.
Kline, Douglas J., 383 West 52nd St., Trenton 8, N. J.
Kretzer, Sherman N., USPHS Hosp., 210 State St., New Orleans 18, La.
Kron, Richard Conrad, 625 Southdale Medical Bldg., Minneapolis 10, Minn.
Krupnik, Joseph, New England Center Hosp., Harrison Ave. and Bennett St., Boston 11, Mass.
Krupnik, Albert, 180 Lincoln St., Worcester 5, Mass.
Larson, Thompson, 1001 East Pennsylvania Mental Hygiene Clinic, 1501 Fifth St., Newport News, Va.
Leah, Frederick A., Jr., 5616 East Bakes Ave., Denver 22, Colo.
Leah, Lawrence, 100 Indiana University Medical Center, 100 West Michigan St., Indianapolis 2, Ind.
McIntire, George A., 215 South Painter Ave., Whittier, Calif.
Mack, Aladar T., Cleveland Regional Treatment Center, 11, 90 Lorain Rd., Cleveland 10, Ohio.
Marshall, Marion G., Schenley Park Apts., Fifth Ave. and Schenley Blvd., Pittsburgh 18, Pa.
McGraw, William W., Jr., 1750 High St., Denver, Colo.
McDonald, Marjorie, Hanna Pavilion, University Hospitals, Cleveland 6, Ohio.
McKee, Douglas, 2109 Clara Ave., Raleigh, N. C.
Meadows, Richard L., Topeka State Hosp., Topeka, Kan.
Meyers, Edward F., 520 N. Main St., Orlando, Fla.

BOOK REVIEWS

THE SANCTITY OF LIFE AND THE CRIMINAL LAW. By *Glanville Williams*. (New York : Alfred A. Knopf, 1957, pp. xxii + 350. \$5.50.)

Professor Williams is a Fellow of Jesus College, Cambridge. In 1956 he delivered the James S. Carpenter Lectures during his term as Visiting Professor on the Faculty of Law at Columbia University, New York City. This book presents an amplified version of these lectures.

It is a courageous book. It considers questions of "legal biology and legal ethics," the function of the law in the service of man and for his protection, and desirable changes in the law to that end.

The titles of the 8 chapters : The Protection of Human Life, The Control of Conception, Sterilization, Artificial Insemination, The Law of Abortion, The Problem of Abortion : Morality and the Social Facts, The Prohibition of Suicide, Euthanasia, will indicate the highly controversial nature of the material the author deals with. He presents fully the factual background of these various issues and seeks to keep their treatment objective. He does not hesitate however to express his own considered opinion on matters where, so far, there is no consensus. It is these opinions that give the book its special value.

In each of these chapters the author considers the problem involved from the standpoint not only of British law but also of law in the United States and other countries ; and where existing legislation does not minister to social welfare and is inhumanly prejudicial to the welfare of the person who may be accused thereunder, he points clearly to the need for change. In the case of infanticide by the mother, for example, where so many extenuating circumstances may exist, he asks for "greater exercise of the discretion of prosecuting authorities," and reminds us that "one element in the legal process is ineluctable—the distress of mind caused to the offender by being summoned before a court, particularly where this involves much publicity in the press. This reinforces the argument that a legal inquisition into conduct is not justified on moral or religious grounds if no sufficient or social purpose is to be served."

Recalling that Malthusian prophesy is being frighteningly fulfilled in our time, and that "already two-thirds of the world's population are living pitifully on or below the margin of

subsistence," Professor Williams calls for sane laws dealing with birth control, which at present largely disregard the rights and well-being of the female half of the population. He quotes an American survey in 1943, when 85 percent of women questioned favored contraceptive advice for married women as did more than 2/3 of the Catholic women questioned. And he points out that "it is the religious objections that have done so much to retard medical exploration in this field of knowledge. When religious opinions are embedded in the law, the cramping effect upon free scientific enquiry is even more disastrous." Of the religious argument that contraception is "against nature" he remarks, "This extremely primitive if not blasphemous theology can perhaps be sufficiently answered by pointing out that nature evidently intends males to have beards, which intention they steadily frustrate by the use of the razor."

The question of artificial insemination "is not specially dealt with either in American or English law." The author surveys the range of rulings and opinions, both legal and theological, which are rather more curious, sometimes amusing, than edifying.

The law concerning therapeutic abortion has become considerably softened in recent years. Under the National Health Service in Britain, a large London hospital reported that in the year 1953, 46 therapeutic abortions had been performed, as compared with 9 in 1938.

Though opinions are divided, Protestants and Jews generally are favorable to therapeutic abortion. "The Church of Rome, on the other hand, remains adamantly opposed . . . even to save the life of the mother." For comparison turn to Japan where sterilization and abortion for medical, economic or eugenic reasons were legalized in 1948. For the year 1954 operations under this law numbered 1,143,059. In Scandinavian countries abortion is authorized on much wider grounds than strictly medical. In Denmark pregnancy may be terminated to prevent serious danger to the life or health of the woman based on "(1) present physical or mental illness ; (2) threatening physical or mental weakness ; (3) the social circumstances under which the woman has to live."

A scholarly chapter deals with attitudes to suicide from early times on, and with punishment for attempted suicide in various countries. Thomas Aquinas held that since man was the property of God, only God could de-

cide on his life and death. Seneca on the contrary, had asserted the jurisdiction of the individual over his own life.

Attempted suicide is not an offence in Indiana, Iowa, Maine, New York, Pennsylvania; it is also unpunishable in Ohio, Illinois and Texas.

The final chapter discusses a particularly controversial subject—euthanasia. The author reviews opinions and rulings, legal and theocratic, and points to the opinion expressed by the Catholic Sir Thomas More, in his *Utopia* where any that are "taken with a torturing and lingering pain, so that there is no hope either of cure or ease, the priests and magistrates come and exhort them that, since they are now unable to go on with the business of life, and are become a burden to themselves and all about them, and they have really outlived themselves, they should . . . choose rather to die since they cannot live but in much misery."

Professor Williams presents and accepts the view that "a man is entitled to demand the release of death from hopeless pain and a physician who gives this release is entitled to moral and legal absolution for his act."

To sum up: a fully documented statement of existing laws relative to some of the most vital concerns of human existence, and the author's enlightened and humane attitude thereto.
C.B.F.

A SKEPTICAL PSYCHOANALYST. By *Kenneth M. Colby, M. D.* (New York: Ronald Press, 1958. pp. 145. \$3.75.)

TECHNIC AND PRACTICE OF PSYCHOANALYSIS. By *Leon J. Saul, M. D.* (Philadelphia: Lippincott, 1958. pp. 244. \$8.00.)

Growing fascination with new drugs and increasing interest in brain physiology have taken some of the spotlight from psychoanalysis. However, psychoanalysis still continues to enchant new entrants into psychiatry; and veteran practitioners show no flagging of loyalty.

These two new books reflect the continuing interest in psychoanalysis. Dr. Colby's work is a medley of marginalia, a collection of witty footnotes on psychoanalysis. Dr. Saul's text is a systematic handbook of technic. Dr. Colby's essay on "Why Newton Hated Apples" is a bouncing burlesque of solemn science writing, as well as a charming bit of whimsy. His "Letter to a Young Analyst" is wise as well as witty. He makes pungent remarks about organizations, about psychoanalysts, about medical journalism, and about interprofessional relations. He salts his text with many Colby-

isms. (Example "psychoanalysts like to say that they are only human but they don't really believe it.") He offers an ingenious technic for self-analysis with a tape recorder (strictly for professional use however; he does not believe in extending do-it-yourself to the patient.) He notes how we overemphasize resistance but have little to say about facilitation of analysis—and he coins a new word for this ("proceedance") and suggests how it may be improved.

Dr. Colby is one of the few psychiatric writers to be interested in the inner thought processes of the analyst. What the book lacks in organization, it makes up in sagacity. It is a pleasant night-table volume—and is a good gift to a friend interested in psychoanalysis, professionally or personally.

Dr. Saul is a practitioner with a superior sense of the analyst's social responsibilities. He offers a better-than average account of how to get anamnestic data. He includes an interesting discussion of the mechanics of analysis. His little essay on the couch is a monographic gem. Unlike many of his brethren, he recognizes that some patients can become addicted to psychoanalysis. I think he heckles the reader with footnotes—there are at least 65 citations to Freud alone, and in less than 250 pages of text he has some 120 footnotes.

The book is beautifully constructed with chapters on failures, difficulties, transference, dream analysis, free association and on the technics of starting and terminating treatment. One of the nice parts of Dr. Saul's book is constant re-orientation to reality. He does not make a fetish out of dogmatism.

American psychiatric literature is well supplied with books on psychoanalysis. But Dr. Saul and Dr. Colby each offer us a fresh point of view. In its short life, psychoanalysis has developed a doctrinal caking that sometimes subordinates the patient to the theory. These two books are healthy antidotes to such ritualism.

ELEKTROENCEPHALOGRAPHISCHE STUDIEN BEI HIRNTUMOREN. (ELECTROENCEPHALOGRAPHIC STUDIES ON BRAIN TUMORS.) By *Rudolf Hess.* (Stuttgart: Georg. Thieme, Verlag, 1958. pp. 106. \$4.20.)

Hess' study is based on the analysis of the electroencephalographic records of 682 verified and localized brain tumor cases from Krakenbühl's Neurosurgical Clinic in Zürich. It deals with the relationship between localiza-

tion and the EEG changes. The different types of diffuse and focal electroencephalographic abnormalities observed are described in detail and correlated with the various tumor sites. It is not concerned with the influence the nature of the tumor and its growth might have on the EEG. The study, however, is not purely statistical. Important practical and theoretical conclusions are offered. The findings of former investigators are discussed and largely confirmed. In some instances older views will have to be modified on the basis of Hess' broader material. In this reviewer's opinion the main value of the present study consists, aside from the extensive material on which it is based, in the extreme caution which the author applies in his conclusions modestly called hypothetical.

THERAPEUTIC EXERCISE. Edited by Sidney Licht, M. D. (Baltimore, Md.: Waverly Press, 1958. pp. 893. \$16.00.)

This book, the third volume of the Physical Medicine Library Series, is an excellent collection of 35 articles describing in detail the values of correctly prescribed exercises primarily in muscular or neurologic disorders.

In the chapters covering Occupational Therapy and Sports very little is stated concerning their use in psychic disorders. However, the chapter, Exercise in Mental Disease, by John Davis, Ph.D., formerly with the Veterans' Administration, indicates clearly how an individually prescribed therapeutic program can aid in reintegration and socialization. Specific exercises and games are suggested for each type of illness and these activities are described in detail. The closing chapter should be of interest to everyone, as it deals with Exercise for Healthy Persons and describes proper postures for sitting, standing, lifting and even sleeping. This book is a valuable reference for any condition requiring muscle training and reeducation.

ROBERT S. SCHOPBACH, M.D.,

THE HANGOVER. By Benjamin Karpman, M. D. (Springfield, Ill.: Charles C Thomas, 1958, \$9.50.)

This voluminous treatise on the hangover consists of personal accounts of what 14 patients consider a hangover, much of it in quotation marks. There are 7 male and 7 female so-called case histories, but all except one con-

sists only of subjective reminiscences of the trials and tribulations during varying periods that followed their alcoholic sprees or binges. These experiences are called "the hangover" which is not otherwise defined. These episodes vary from what the average non-alcoholic person might consider a hangover, namely the period of malaise and ill-feeling with or without specific bodily symptoms which may last a fraction of a day, to periods stretching into days and weeks, covering the whole range of alcoholic symptomatology including in some instances hallucinosis, delirium tremens, and other types of psychotic behavior, even fugue states. The book proves without question that whatever alcoholics call the hangover or in general the post-spree period is one of greatest misery and self-torture, not to mention the accompanying unpleasantness for whom-ever may be around the patient at that time. It is an indication of the seriousness of these patients' illnesses that most were isolated, had no relatives or friends to whom they could turn and usually were dependent in their misery upon the public caretaker agencies, the police, landlords, and public hospitals.

Most of the stories are well written, some fascinating but even then they are no more than autobiographical sketches and quite sketchy in many instances. None affords as much insight or makes as good reading as Jackson's *Lost Weekend*, in which one can find almost everything that is to be found in this book.

A serious defect of the book is that there is no description of method whatsoever. Only in the acknowledgment in which the author expresses his appreciation to his patients does one learn in passing that the material was obtained from written accounts and from interviews. Presumably the interviews were all the author's, but this is not so stated, nor the type of interview. In no case is a distinction made as to which material was written by the patient and which was obtained in interpersonal process. The author is, therefore, justified in keeping the section of interpretation which follows each case history limited essentially to a brief summary of what the patient has communicated, and none of these interpretations extend to much over 1 to 2 pages. To the reader, material of this kind remains scientifically meaningless, except for random speculation, because the context in which the material was obtained is not presented and the relation between interviewer and interviewee is not defined.

The author's thesis that a personality dis-

order underlies alcoholism in every case, with which the reviewer agrees—is neither supported nor refuted by this book. Only in one case of the 14 was treatment brought to a **satisfactory conclusion in the sense** that the patient herself understood the roots of her difficulties which led to drinking, and at least her story implied that she had resolved some of her basic conflicts and changed her attitudes and behavior. Almost all the other patients paid lip service to the author's thesis, but the author himself repeatedly points out how "unreliable" their accounts are. Obviously to write these accounts the patients must have had a relationship with the author or somebody and the skeptic can easily suspect that therefore the patient would write whatever formulation would please the interviewer. The author has demonstrated, however, that the period called here the hangover can be used, if sufficiently remembered by the patient, somewhat like a projective test or a drug interview because in this situation the patient's mental difficulties apparently come more into consciousness than at other times and are available, therefore, for verbal or other behavioral communication.

STEPHEN FLECK, M.D.,
New Haven, Conn.

THE MATRIX OF MEDICINE. Edited by *Nicolas Møller*. (London: Pitman Medical Publishing Company, 1958, pp. 234. \$9.00).

This book, more clearly than any other which I have seen, demonstrates the changing nature of medical practice, especially the growing recognition that medicine (and the patient) is embedded in a social matrix of great consequence to its activity.

The editor, a University physician, has collected 13 chapters by practitioners of unusual perception in fields ranging from endocrinology to chest disease. They each show in a lively style the intimate relation between practice and social conditions, and demonstrate the necessity to take these into account. For example, the discussant of industrial medicine strongly questions the usefulness of the routine physical examination in modern industrial conditions; a heresy which he supports admirably.

It is unfortunate that there is no contribution from psychiatry, the field most directly affected by society, but the entire volume is a measure of the success of teaching concerning the personality, and in some ways may demonstrate how a pupil may threaten to outstrip a tutor.

This is recommended reading for all who

believe that psychiatry is a field of social and socialized medicine.

BRYANT M. WEDGE, M.D.,
London, Eng.

READINGS IN MEDICAL CARE. Edited by the Committee on Medical Care Teaching of the Association of Teachers of Preventive Medicine. (Chapel Hill, N. C.: Univ. of North Carolina Press, 1958, pp. 708. \$6.50.)

Medical care is a term used with reference to the organized provision of medical services to the populace. Whereas the standard of medical skill in the United States is of the highest calibre, many of the citizens received inadequate medical care chiefly because of economic and geographic hindrances. This book deals with the extent of the problems of providing adequate medical services, the ways in which attempts are being made to improve medical care and the ideals toward which group endeavours should aspire.

The book is a collection of reprinted portions of articles and books by a variety of authors. The purpose is to present teaching material on the organization of medical care. To this end over 120 "readings" have been arranged under the headings:

1. Problems in Medical Care: The General Background;
2. The National Health Picture;
3. Adequacy of Medical Care;
4. The Costs of Medical Care;
5. The Medical Care Team;
6. Hospitals;
7. Co-ordination in Health and Medical Service;
8. Care of Long-term Illness;
9. Rural Medical Care;
10. Public Medical Care;
11. Medical Care in Industry;
12. Medical Care Insurance;
13. Principles and Proposals.

Most of the writings are informative but few are inspiring. In some sections statistical data numbs the brain, in others tedious repetition or labouring of the obvious dims one's interest. To attempt consecutive reading is to court mental indigestion. In fact, were it not that the result is an exceedingly useful source book for references, one feels that the collection of writings might make the basis for a good book if someone had the energy and talent to write it.

Psychiatry receives less attention than the problems of mental illness deserve—less than 20 pages of 708. Perhaps the Association of Teachers of Preventive Medicine are less familiar with mental illness than with, for example, industrial medicine or the rehabilitation of physically-handicapped people.

The sections devoted to Health Insurance

deserve study. The forces which have resulted in State Health Insurance in many countries are obviously at work in the United States, the most prosperous country in the world.

The book will be of great value to anyone responsible for planning the provision of medical services on a large scale or to teachers in the field of Public Health.

W. B. SPAULDING, M.D.,
Toronto, Can.

MENTAL AND PHYSICAL ILLNESS AMONG PAUPERS IN STOCKHOLM. By *Gunnar Inghe*. (Copenhagen: Ejnar Munksgaard, 1958.)

"This Report is part of an investigation concerning the condition of persons in receipt of public assistance in Stockholm, and of the causes of their predicament." An introductory statement of the problem, gives some interesting historical material. Then follows a short review of previous surveys. A section of this, dealing with mental illness is particularly good, and complete. The summary is as follows—"This short survey shows that paupers deviate considerably from the general population in medical respects. Both the mental and physical morbidity are probably very excessive. It is, however, still not fully known which illnesses are particularly frequent."

Then follow a chapter dealing with different concepts of morbidity and one on statistical methods. Next comes a chapter on the subjects of the survey, a description of Stockholm and the selection of the paupers. A control group was matched with the pauper group. An attempt was made to find a "social twin" for each pauper. We have married, single and cohabiting persons—somewhat of a surprise to American readers! Next comes a method of obtaining data from interviews, medical examinations and from histories. Just how the mental diagnosis was made is not entirely clear. That there were defects in the material is readily acknowledged.

Chapter 6 deals with mental illness; a number of case histories are given. The term mental insufficiency is used, apparently much as the term *neurosis* would be used in this country. Insufficiency is described as conditions characterized as uneasiness, anxiety, despair, irritability, depression, feelings of discomfort, discontent, compulsive symptoms, feelings of strain and stress or other nervous manifestations. One questions whether this term is a proper substitute for the modern concept of the *neurosis*. The fact that 81% of the male and 64% of the female paupers were suffering

from mental disorder at the medical examination is significant, also, 1.3% of the males and 27% of the females among the controls.

"In summing up it may be said that the differences between the samples regarding the prevalence of, and risks for different mental illnesses were somewhat variable. This perhaps was partly due to the small samples. On the whole, however, the morbidity was higher for the paupers than for the controls. This applies to all the main groups of mental illnesses, even if the differences were not always significant."

There follows a similar study of physical disease. The resume and conclusions are printed in French and Russian at the end of the book. There is an elaborate and extensive bibliography.

WARREN A. STEARNS, M.D.,
Billerica, Mass.

NEUROPATHOLOGY. By J. G. Greenfield, W. Blackwood, A. Meyer, W. H. McMenamy and R. M. Norman. (London: Edward Arnold, Baltimore: Williams and Wilkins, 1958, pp. 640. \$20.00.)

An outstanding feature throughout the history of neuropathology has been the value of the contributions made by investigators whose primary interest was not pathology—by neurologists, neurosurgeons and psychiatrists. The names of Alzheimer and Nissl, both of whom were practising psychiatrists, are firmly embedded in the terminology of the subject. More recently, general pathologists have been taking increasing interest in this branch of pathology. In Britain, neuropathology has always largely stemmed from general pathology, and this broad outlook is evident in the present book which is the work of 5 eminent British neuropathologists led by the late Dr. J. G. Greenfield. Although much has been contributed by his collaborators, the book may well be regarded as the culmination of Dr. Greenfield's long and illustrious career.

The book gives a systematic account of the pathology of neurological disease other than tumours. In the preface we are promised a companion volume, dealing with tumours of the nervous system, edited by Professor Dorothy Russell. The main emphasis throughout is on classical descriptive histopathology, but the authors give brief clinical outlines and refer to experimental data in some instances. Biochemical findings are also discussed, for example abnormalities of copper metabolism in the account of Wilson's disease.

The work opens with a chapter by Dr. Greenfield on the various reactions of nerve

the brain, especially in lesions of a more extensive or subcortical nature, in which the localization of lesions with the help of the study of motor topography, is confined to study by field type maps available. These tables are arranged by Piek and the author in a simple manner. The appearance of the drawings of some other hemispheres and cerebral fiber tracts, in some of the pages, and the remaining pages is devoted to maps and drawings. He is less clear in his description of the motor fiber tracts of the brain in comparison with the more detailed studies in the pathogenesis of cerebral atrophy of the brain.

In the last, Meyer reviews a wide field of subjects, the study and the effects of various types of lesions, cortical, subcortical and mixed, giving evidence of regions, consequences and signs. In a chapter on Spina, he discusses the anatomy of the spinal cord, the temporal axis, he includes in the text that which would have been omitted in the rest of the book, both in the anatomy and in the clinical course. None can deny the statement that he used the further investigation of the problem, being post-mortem material in addition to clinical specimens, so as to make possible a complete survey of the motor system.

In a somewhat brief chapter, Meyer collects the opinions of various investigators regarding a possible morphological substratum for schizophrenia and certain other psychoses. He points to the lack of controls in the series described by some investigators and to the frequent failure to consider the effects of concomitant disease in chronically ill, debilitated patients. The original demonstrations have proved a more rewarding subject for pathological study: the lesions associated with the names of Alzheimer, of Pick and of Jakob and Creutzfeldt are described in detail and fully documented in a chapter by McMenemey; he also discusses Huntington's chorea. Included in this chapter are short sections by Greenfield on hypodenticular degeneration, and by Meyer on the Huntington-Spatz syndrome.

A superbly illustrated chapter by R. M. Norman, on developmental malformations, birth injury and diseases of early life covers in masterly fashion the wide range of conditions in this essentially clinical grouping.

Also included in the book are chapters on demyelinating disease, the system degenerations, the peripheral nerves, trauma and the effects of disease of the bony coverings of the nervous system, all written by Greenfield and illuminated by his vast experience.

Throughout the work, the importance of the subject is detailed and especially history, was a stimulus to the historical approach. The authors have reviewed personal experience and literature. There is a good summary and the reliability of the data for the purpose of administration. The language throughout is brief. Nevertheless the book is an excellent source for those who wish to gain a rapid impression of cerebral changes with one glance. Thus the book is a fine addition rather to the present as a first reference and source of further reading in the original literature. It should also prove a valuable basis of reference for students and practitioners. The volume is particularly the reproduction of the photographic is excellent. The binding is bound stand up to the heavy and constant use the book will receive from all serious students of the nervous system. The work is the most detailed and authoritative monographs on motor pathology available in the English language.

THEORY AND METHODS OF SCALING. By William S. Jungerson. New York: John Wiley & Sons, Inc., 1958. pp 460. \$9.50.

Psychological scaling methods for the measurement of attributes have been developed in a variety of fields. This book is a most serious endeavor to bring the many methods, but not together. It was prepared for the Committee on Scaling Theory and Methods of the Social Science Research Council and contains material which previously was only available in isolated articles and special book chapters.

In addition to examining established scaling procedures, the author presents subject matter based on his own work in the field. This includes a least-squares solution for the constant sum method, alternative solutions for the categorical judgment model, a multidimensional model for quantitative judgments, and a general normal ogive model for response data.

Scaling procedures have proven to be helpful in studies of discrimination, learning, generalization and personality. Research workers in the various social sciences should profit from a reading of this contribution. Mathematicians and statisticians are given further stimulation to continue their interests with much-needed theoretical frames of reference.

ARTHUR LERNER, Ph.D.,
Los Angeles City College.

IN MEMORIAM

SEYMOUR D. VESTERMARK, M.D.

1902-1959

The outstanding training program of the National Institute of Mental Health stands as a memorial to the late Dr. Seymour D. Vestermark, who, from 1946 to 1959, was Director and then Chief of the Institute's Training Branch. Since the time it was founded in the late 1930s, starting at a time of rapidly increasing demand for professional personnel in the mental health diagnosis and when few centers offered such training, Dr. Vestermark organized a national program for promoting more and better opportunities for training in psychiatric clinical psychology, psychiatric nursing, psychiatric social work; and training for research related to mental health. By providing assistance through grants and professional consultation to help institutions develop and expand training centers, the program has greatly increased and enhanced educational opportunities in psychiatric and other mental health disciplines.

So great was Dr. Vestermark's contribution that he was cited by The American Psychiatric Association, in January 1959, for having "exerted, during his assignment, a greater influence in the field of psychiatric training than any other person."

"For a decade," the citation continued, "Dr. Vestermark has, by virtue of his personality, his sound psychiatric background, his constructive imagination, and his sound judgment in the distribution of public

funds made available for this purpose by the Congress of the United States, greatly increased the number of students training at medical schools in the field of psychiatry and the better development of psychiatric research training. Recognizing the importance of this activity, the Association has elected Dr. Vestermark a corresponding member, and has presented a letter of appreciation of psychiatry with the Association and the basic sciences."

Dr. Vestermark was a full member of the American Board of Psychiatry and a Fellow of The American Psychiatric Association. He also was a member of many professional committees and conferences in psychiatry and in 1948 served as United States Delegate to the International Congress in Neurology in Lugano, Switzerland.

Born in Dallas, Tex., Dr. Vestermark was a graduate of Case College and the Medical School of the University of Iowa and took postgraduate work at the Colorado Psychiatric Hospital in Denver. He was commissioned in the Public Health Service in 1932 and served as Chief of the Neuropsychiatric Service at the Marine Hospital on Ellis Island and as Executive Officer of the U. S. Public Health Service Hospital in Fort Worth, Tex., before going to the National Institute of Mental Health.

Harold P. Halpert
Nat. Inst. of Mental Health

RICHARD BRICKNER, M.D.

1896-1959

As a physician, Richard Brickner conformed to the definition of Robert Louis Stevenson of a good doctor, for "he brought air and cheer into the sickroom, and often enough though not so often as he wished, healing." As a medical scientist, his many contributions to neurological literature were

invariably of high quality. He achieved distinction, however, and I may say great distinction, in two areas. One was in his approach to multiple sclerosis. Greatly disturbed by the black prognosis for the sufferers of this disease, he dedicated himself to the study of its many problems. He

was eclectic in his method of attack. He applied his boundless energy toward this goal, and approached it from every angle. He was largely responsible for the establishment of the Multiple Sclerosis Association. He stimulated research in a hundred laboratories. He literally dragged the disease from the back wards of hospitals for chronic and incurable neurological diseases and pinned it to the stage of a microscope. **If ever a solution to the problem of multiple sclerosis should be found, this will be a superstructure on a foundation which he has helped to build.**

The second area in which Richard Brickner achieved distinction was in the physiology of the frontal lobes. We were sharing an office together when he first became acquainted with a patient who had had both frontal lobes removed along with the tumor which had invaded and partly destroyed them. He immediately recognized the important physiological implication of

such an operation, and spent years studying the neurophysiological and psychological deficits resulting from it. It was undoubtedly his report on this case, which was published in a detailed monograph, that stimulated the invention of bilateral frontal lobotomy by Egaz Moniz, for which he eventually received a Nobel Prize.

His one assay into semi-popular literature took the form of a book entitled *Is Germany Incurable?* While many people took issue with his conclusions and the book aroused a considerable amount of controversy, it served to stimulate a good deal of thinking about the psychology of the German people which permitted the rise of a Hitler.

In all that Brickner did he put his whole heart and soul, and although he was invalided for several years before his death, he maintained an active interest in a dozen problems right up to his last breath.

Leo Davidoff, M.D.,
New York City.

RELATION BETWEEN HISTORY, PERSONALITY AND FAMILY PATTERN AND BEHAVIORAL RESPONSE AFTER FRONTAL LOBE SURGERY¹MILTON GREENBLATT, M.D.²

The lobotomy studies of the psychosurgical period afforded an excellent opportunity to investigate the relationship between behavior after brain damage and a large number of variables related to history, personality, and background.

For the purposes of our discussion, it would be most fortunate if the frontal section produced by the operation were uniform from patient to patient. Unfortunately, this is not so. Even where the surgical intent is the same, and the procedure held, as far as possible, constant, the lesion probably varies considerably. Skulls vary, brains vary anatomically and functional organization—whatever there is of it in the frontal lobes—also varies. A conservative surgeon has stated that with the best planning the plane of the section could easily vary by as much as one centimeter. Clearly this could make a tremendous difference in the pattern of fibers cut and in the ultimate reorganization of personality in response to brain lesion.

In my first discussion I will draw upon a series of cases of chronic psychosis from lobotomy studies carried out between 1943 and 1949 (1). During this period the operative lesion was a full bilateral cut performed *via* a superior opening just anterior to the sagittal suture with all technical procedures under direct visualization (Poppen's technique). A careful analysis of traits or "factors" was done before and after operation. Thirty factors were studied, selected on the basis that each was relatively objective, readily observable, and could be easily rated or quantified. In speaking of the changes, we think of them as changes

"following operation" rather than caused by operation. This seems like reasonable scientific caution, since changes under these circumstances are complexly determined.

One of the most important discoveries of this study was that with almost all factors there appeared a shift in two directions: a group of patients who were "abnormal" in respect to a trait becoming "normal" after operation; and, conversely, a group who were "normal" before operation becoming "abnormal" after operation. Our data are based on 181 patients followed up 1 to 4 years after surgery. In some instances, the abnormal characteristics existing preoperatively disappeared altogether postoperatively with no symptom of this type appearing in any cases for the first time following operation. In other instances, the abnormal symptom receded markedly or disappeared postoperatively in a large percent of the cases but appeared for the first time in a small percent of cases; and in a final group, the shift in the normal direction was more than overbalanced by a shift in the abnormal direction.

Figure 1 illustrates those areas where, in our experience, the most reliable prediction of change in a favorable sense may be made. Virtually no patient developed postoperatively the symptom or trait designated, and a very large proportion of those who had these traits preoperatively were relieved by operation. If this were the sum total of changes produced, certainly lobotomy would be more popular today than it is.

Let us now turn our attention to a group of manifestations that are to a large degree improved by operation but where there is a definite risk of producing an undesired change postoperatively as well.

Figure 2 shows 5 factors in which there is not only expectation of good results, but also a chance that undesirable changes will occur, too. In the case of "Alcoholic Excess," of 6 patients who could be put

¹ Read at the 114th annual meeting of The American Psychiatric Association, San Francisco, Calif., May 12-16, 1958.

² Assistant Superintendent and Director of Research & Laboratories, Massachusetts Mental Health Center (Boston Psychopathic Hospital); and Associate Clinical Professor of Psychiatry, Harvard Medical School, Boston, Mass.

FIGURE 1

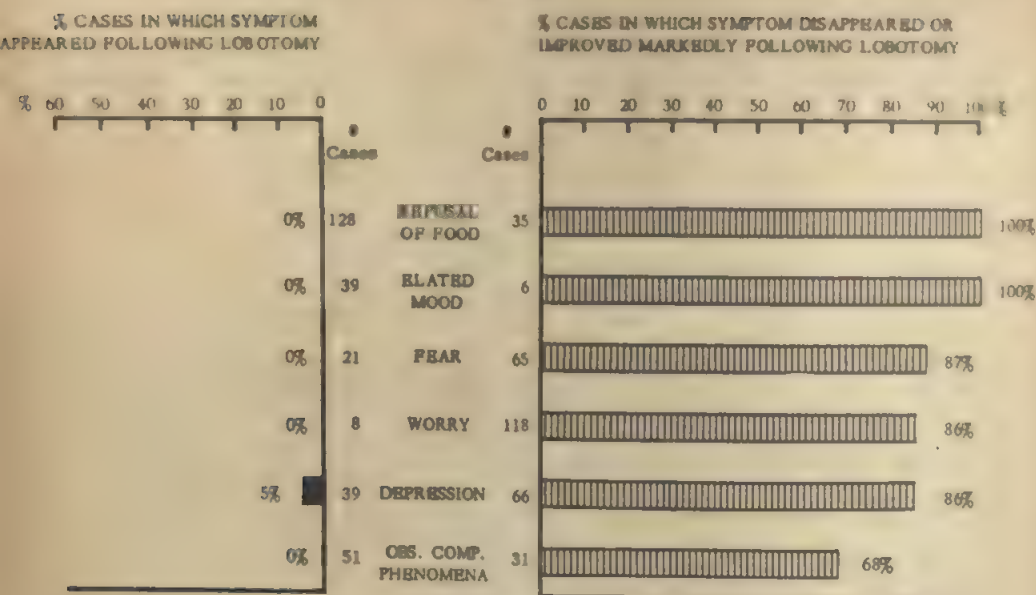

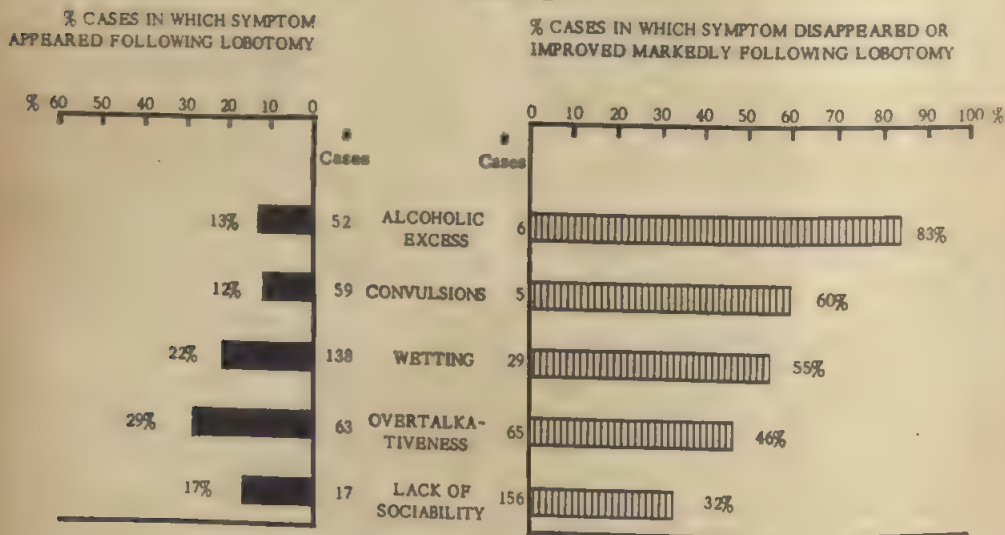

FIGURE 2

in this category preoperatively, 5 were relieved entirely of their alcoholism postoperatively. However, of 52 who were clearly non-indulgent, 7 (13%) increased their consumption significantly postoperatively. In a separate publication(2) we studied in detail the question of alcoholism in a larger series of cases with the following conclusions: 93% of lobotomized patients who returned to the community did

not change their drinking habits. Those who did usually changed markedly, going from one extreme to the other. Five patients (3%) out of 167 non-alcoholics became alcoholic for the first time after lobotomy. Three (25%) out of 12 known alcoholics stopped drinking entirely. Four (33 1/3%) of the 12 drank more after lobotomy than previously; and 5 (41%) were unchanged in their drinking habits.

The social problem of the small group who drank excessively, however, was often severe since they were less tolerant of alcohol, more hostile, insensitive and anti-social.

It is interesting to know that although in this group the risk of convulsions after operation was in the neighborhood of 12%, nevertheless 5 of 6 well-established epileptics were markedly improved in terms of the frequency and severity of seizures. In the former, the convulsions may be understood as at least partly "caused" by brain damage; in the latter, our hypothesis is that convulsions were related to tension and emotional difficulties which were allayed by operation.

With wetting, which has been defined as incontinence (frequent or infrequent, one month or more after operation) some 22% of patients formerly continent became wetters, yet 55% of those who were wetters as part of their psychotic state were relieved of this symptom.

The next 2 items, overtalkativeness, and lack of sociability, reflect lack of social refinement and restraint commonly found in patients after full bilateral operations.

Figure 3 shows 4 areas in which the degree of improvement is overshadowed by the production of undesirable effects. We find that excess appetite, irritability, outspokenness, and deficient insight are more often produced than reduced by operation.

Thus, psychosurgical treatment must be understood in terms of its double potential—to "normalize behavior" and to "abnormalize" behavior. Changes clearly can go in different directions and "undesirable" manifestations in a given dimension may be more pronounced than "desirable" manifestations. This terminology inevitably involves us in the problem of *evaluation* of change, a complex matter that cannot be considered fully here. The issue, however, is so important as to warrant discussion in at least one of its dimensions of consideration.

We have learned that the degree of satisfaction felt as the result of given personality changes following psychosurgery is in large measure a function of family dynamics. For example, some 25 cases were studied where after operation a husband or wife returned to live with the spouse. Many of the changes in family relationship in this context could be seen as subsequent to changes along theoretical "aggression-submission" axis. It was possible to demonstrate that in some instances the husband-wife relationship was rendered more comfortable and, in other instances, less comfortable by a shift in the spouse, either towards the aggressive or towards the submissive end of the continuum.

Thus, Mrs. K, a 70-year-old, married, childless woman, had considerable drive, energy and responsibility, while her husband who was unambitious did odd, unskilled jobs

FIGURE 3

% CASES IN WHICH SYMPTOM APPEARED FOLLOWING LOBOTOMY

% CASES IN WHICH SYMPTOM DISAPPEARED OR IMPROVED MARKEDLY FOLLOWING LOBOTOMY

around the house and drank a good deal. Mrs. K met interesting, influential people on her job and received much attention because of her pleasing personality. At home she was the "boss" of the family. However, when her job was terminated during an economic depression, she promptly fell into an agitated state, full of anguish, hand-wringing and pacing. This lasted undiminished for 8 years.

Following operation, all symptoms disappeared but unfortunately the patient took little interest in her appearance, her job or her housework. She seemed content and relaxed and turned over all responsibilities to her husband who in turn was delighted by the change, joyfully accepted the new duties, did not complain of her laziness, and even stopped drinking. The decrease in energy and tension of his wife seemed to give him the feeling of adequacy and masculine dominance he needed.

By contrast, consider the H family in which the wife was almost the twin of Mrs. K—elderly, childless, domineering, energetic and successful before the onset of her illness which was characterized by crying, somatic complaints and agitation. After operation she was lacking in energy or initiative. Her husband complained, "She is hopelessly lazy; I might as well be a bachelor." He grudgingly did the housework, cooking, *etc.*—all the things that Mr. K had enjoyed. He became disgruntled, thin, unhappy; but his wife was cheerful and no longer wept. She seemed content although she expressed some dissatisfaction concerning her lack of energy.

Similar examples could be quoted illustrating how an *increase* in energy and aggressiveness of a partner following operation was welcomed by one spouse or greeted with consternation by another.

In our early series there were some 36 patients who, after operation, returned to live with parents. Although their ages varied from 16 to 45, we think of them as "children" in the family structure. Here we may conceive of changes as taking place along a theoretical axis of "dependence—*independence*." Most children, 33, became more dependent; a few, 3, became more independent. Some children, 7, who had established separate living prior to lobotomy returned to live with their families after operation. They became economically as well as emotionally dependent upon their families which led to more disturbance

than in those instances where patients had formerly lived with parents and after operation returned to the same setting.

Among the instances of increased independence may be mentioned:

One attractive manic-depressive female became engaged, married and moved to another state where she adjusted well.

One passive-submissive son for the first time after operation was able to voice his antagonism to his father to the surprise of his parents, and one day, in typical Hollywood fashion, he made a dramatic exit from the family home in the middle of a blizzard. The patient has been self-supporting and said, "It made a new man out of me." He has never been reconciled with his father.

The third patient lived with the mother who died while she was hospitalized. After trying unsuccessfully to live with her brother, she then made it alone in a rooming house, supporting herself on her own job, even receiving a raise.

Parents of younger children may be considered in the light of how well they reared their offspring after operation. Our best data concern a group of 14 mothers studied by Greta Sharaf (3). Of these, 5 fulfilled the role adequately, 3 partially, and 6 failed completely. These 5 are of special interest apropos the question of the effect of radical brain lesions on maternal behavior. It may be surprising to some that two parents formerly preoccupied with obsessive details, cleanliness, and self-imposed standards so as to be unable to care for children, after operation were more relaxed, affectionate and secure in their relationships. Others, however, did not fare as well.

We see above opposing trends in clinical change as well as varying effects of these clinical changes on family dynamics. Are the changes related to fortuitous and uncontrolled variations in plane or extent of operative section, or are they related to factors existing prior to operative intervention? Data from social interaction studies based on a group of patients studied in 1950-53³ indicate dependence of postoper-

³ These cases received different kinds of operation—bimedial, bilateral, and unilateral frontal sections by the Poppen method.

tive changes in behavior on preoperative characteristics of *social interaction*.

Investigations carried out by J. S. Bockoven(4) on the interaction of patients in an occupational therapy situation both pre- and postoperatively provide us with a clue to social changes for this particular population. First, the overall results.

The results indicate that the statistically average patient increased interaction with his environment after frontal lobe surgery. Specifically, he talked and read more, increased in responsiveness and steadfastness, and carried out more organized actions. He also socialized more with other patients, but showed no change in socialization with hospital personnel; he tended, however, to be more friendly. On the whole the study indicated the average patient became a more active and expressive group member following frontal lobe surgery(5).

Now, what is the relationship between preoperative social behavior and postoperative change? For want of time, I present very briefly the complex findings of Bockoven :

(a) Patients who before operation manifested erratic, constantly shifting, over-productive motor activity, after operation generally moved towards lower energy output and more socially *relevant* activity. However, when the level of energy and activity was extremely low beforehand, there was a release of socially relevant action after operation.

(b) Patients who before operation were characterized as responsive, friendly, or organized in their actions, and inclined to interact with other patients, generally showed great gains in these same characteristics after operation. However, those who were over-responsive, and over-friendly (whose over-sociability was in itself a symptom of a personality disorder) decreased in these manifestations after operation.

(c) The amount of reading after operation bore a reverse relationship to the preoperative tendency to read. Our interpretation is that excessive attention to reading in some instances is a technique of withdrawal from social activity. On the other hand, an increase in reading was noted for those who read very little—in this case,

perhaps the first step in moving toward contact with their environment.

(d) Verbal activity on the whole tended to increase after operation and this in direct relationship to the level before operation.

These complex trends may be crudely summarized by saying that there is, in general, a normalizing tendency. Patients with excessive activity of a non-social type moved towards more socially acceptable behavior as did patients with a marked deficiency in social activity.

Some of the studies from the Massachusetts Mental Health Center have been relevant to the problem of prediction of outcome following surgery. Research-wise this has taken the form of exploring the relationship between specific variables identified before operation and mental status—good, fair, or poor—one year or more after operation. The patient with "good mental status" was one who showed no abnormality in the interview situation and was adjusting satisfactorily in his environment. "Fair mental status" indicated that relatively minor or mild abnormalities in thinking or behavior were present (for example, mild obsessive-compulsive trends or inconstant ideas of reference). "Poor mental status" indicated that the patient had gross defects in mental functioning, such as frank delusions, hallucinations, or deficient memory.

In 1950(1) and again in 1953(6), we published data summarizing our findings on prediction. In the 1950 publication, some 81 factors were correlated with improvement 1 to 4 years after operation, and in 1953 an even larger number of variables were analyzed. I have attempted to boil down the results of both studies and extract only those variables or factors which are of greatest value in prediction. Since the statistical approach in the two studies differed slightly, I am using a fair measure of personal judgment in selecting the variables. Our 1950 publication carries an interesting profile of the characteristics of a theoretical patient most likely to succeed and one least likely to succeed following operation. However, what I present here represents a more refined precipitate of our findings.

The table shows that with respect to

TABLE 1
PREDICTIVE FACTORS FOR

	<u>IMPROVED CASES</u>	<u>UNIMPROVED CASES</u>
<u>ONSET OF ILLNESS</u>	RAPID (ONE MONTH OR LESS)	INSIDIOUS
<u>MANIFESTATIONS DURING ILLNESS</u>	<ol style="list-style-type: none"> 1. AUDITORY HALLUCINATIONS ABSENT 2. INSIGHT PRESENT 3. HIGH "TENSION" 	<ol style="list-style-type: none"> 1. AUDITORY HALLUCINATIONS PRESENT 2. INSIGHT ABSENT 3. LOW "TENSION"
<u>DIAGNOSTIC CATEGORY</u>	PSYCHONEUROSIS--- HYPOCHONDRIASIS OR OBSSSSIVE-COMPULSIVE	DEMENTIA PRAECOX--- CATATONIC OR PARANOID CHRONIC MANIC
<u>SOCIAL BEHAVIOR</u>	<ol style="list-style-type: none"> 1. MORE VERBAL 2. MORE FRIENDLY 	<ol style="list-style-type: none"> 1. LESS VERBAL 2. LESS FRIENDLY

manifestations during illness, *rapid onset* was highly predictive of good outcome as was *absence* of auditory hallucinations, the *presence* of insight and *high tension*.

As for diagnostic category, hypochondriasis and obsessive-compulsive psychoneurosis cases were most likely to improve; however, dementia praecox, catatonic type or paranoid type (essentially chronic), or chronic manic cases, which are probably really variants of schizophrenia, did poorly. In social behavior, those patients who were *more verbal* and *more friendly* tended to improve, while those who were less verbal and less friendly failed to improve generally.

These factors, as we have indicated, were outstandingly helpful in prediction of outcome. Many other factors were helpful in prediction but at a lower level of reliability. For example, if one were married, had children, had obtained a higher education, and if it were possible to identify major precipitating factors in the illness, one was likely to be more helped by operation than if the reverse were true. Patients free of brain damage tended to have better prognosis than those who had brain damage. However, the mere presence of brain damage, if the clinical syndrome

featured tension, *etc.*, did not preclude a good result. A good family, work and community adjustment before operation likewise was of predictive value. The profile thus described in 1950 correlates quite strikingly with the profile recently developed in independent research by Jaco (7, 8) in Texas, and is highly consistent with the findings over many years of our great American pioneer in psychosurgery, Dr. Walter Freeman (9, 10, 11).

It is also interesting to know that relatively good psychological organization, relatively high initiative, good abstraction in psychological tests and an ability to express dissatisfactions in free association were to some extent correlated with good outcome.

In the social sphere, although verbalness and friendliness were the most favorable items, many others at a lower level of predictive value could be mentioned; for instance, ability to express positive and negative affect, or positive orientation to the group versus isolation—in other words, factors that taken together suggest preservation of social extrovertism.

In this communication I do not have time to mention our physiological analyses and the predictive power of straight physio-

logical testing. We were struck by the fact that physiological variables were, on the whole, quite predictive of outcome and feel that this area promises concrete help in our clinical work.

SUMMARY

Studies of many patients before and after lobotomy indicate complex relationships between history, personality and behavioral response after frontal lobe surgery. It has been shown, for example, that postoperative changes may move in either direction along a given parameter—sometimes favorable and sometimes unfavorable. For example, worry and fear were greatly allayed after operation, yet not produced at all by operation. On the other hand, outspokenness existing before operation was removed as a symptom in one-third of the cases after operation, yet in a half of the cases in which it was of no significance preoperatively, outspokenness was *produced* as a postoperative, undesired characteristic.

It is possible to illustrate poignantly how a given change, such as an increase in aggressiveness or dominance, in some instances pleased the family, and in others caused constraints. Conversely, a decrease in aggressiveness or dominance could either please or displease the important persons in the patient's family circle. Social interaction studies showed that there was considerable dependence of postoperative change on preoperative level or type of socialization. In general, the tendency was towards a normalization of behavior: patients who showed excessive activity became more moderate, and patients with deficient activity tended to have a release of this activity after operation.

Concerning the problem of prediction of mental status after operation, it was noted that the primary predictors of good outcome were *rapid onset, high tension, insight present, hallucinations absent, verbalness and friendliness*, and, finally, a diagnosis of psychoneurosis rather than schizophrenia.

The experience suggests that the reactions to severe brain cutting are not to be predicted alone on the basis of the type and amount of brain cut or destroyed, but

in relation to many factors from the background and personality of the patient.

APPENDIX

DEFINITION OF TERMS

Alcoholic Excess

- a. Not present: a teetotaler, moderate drinker, or alcohol "not a problem."
- b. Present: repeated drunkenness causing interference with satisfactory adjustment.

Convulsions

- a. Absent: no epileptiform seizures.
- b. Present: one or more epileptiform seizures.

Fearfulness

- a. Normal: anxiety or tension consistent with reality threats.
- b. Abnormal: constant anxiety or tension out of proportion to reality threats.

Food Intake

- a. Normal: three meals a day without urging or numerous requests for supplementary food.
- b. Inadequate: requires urging, prodding, or tube feeding.
- c. Excessive: large meals plus insistent requirement of supplementary feedings.

Insight

- a. Normal: patients recognized something wrong with them, that problems were psychological or emotional rather than physical; the patient formulated a chief complaint.
- b. Abnormal: patient did not recognize anything was wrong with him. He did not make a chief complaint.

Irritability

- a. Normal: irritation appropriate to the situation.
- b. Abnormal: frequent annoyance disproportionate to the stimulus or situation.

Mood

- a. Normal: absence of abnormal moods defined below.
- b. Elated: obvious marked euphoria, with accompanying gush of speech, with or without overactivity.
- c. Depressed: subjective admission of unhappy affect; patient looked depressed.

Obsessive-Compulsive Phenomena

- a. Present: phenomena such as hand washing, overmeticulosity, or obtrusive possessing thoughts, such as fear of syphilis or germs.
- b. Absent: judged to be within normal limits.

Sociability

- a. Normal: friendly, outgoing.
- b. Lacking: seclusive, withdrawn, avoided normal contacts.

Talkativeness

- a. Normal: near-average number of interchanges; neither reticence nor pressure of speech.
- b. Under: mute or monosyllabic.
- c. Over: constant chatter; unusually rapid flow of speech.

Wetting

- a. Absent: patient not a bed-wetter, not incontinent one month or more after lobotomy.
- b. Present: patient either frequent or infrequent bed-wetter, or incontinent one

month or more after lobotomy.

Worry

- a. Normal: concern over reality issues proportionate to their importance.
- b. Abnormal: constant distressed, disproportionate concern.

DISCUSSION

E. GARTLY JACO, PH.D. (Galveston, Tex.)

—The social dimension in psychiatric treatment has too often been ignored and Dr. Greenblatt is taking a forward step in presenting evidence relating such social factors as family background and social interaction to outcome of frontal lobe surgery.

There is, however, a point to keep in mind about prognosis, particularly with regard to psychosurgery. The group of patients exhibiting a favorable response to psychosurgery as reported in this paper are likely to respond well also to other forms of treatment. Consequently, until controlled comparisons are made between the various forms of lobotomy and other types of treatment, evaluation of psychosurgery as a mode of treatment more advantageous than less severe forms would be hazardous. This was one of the major reasons why a long-term investigation of patients administered transorbital lobotomy, and other types of somatic and drug therapy was initiated in several of the state mental hospitals in Texas several years ago. In comparing matched groups of cases in 3 of these institutions, the outcome both in and out of the hospital of 3 major forms of somatic treatment were studied. It would not be premature at this time to state that within 3 years of follow-up transorbital lobotomy has been the most successful in keeping patients out of the hospital, with chlorpromazine next best, while electroshock and deep insulin, along with custodial care were the least effective.

However, there is another social dimension that I would suspect is operating and affecting the differential outcome of various forms of psychiatric treatment, particularly as it is investigated in psychiatric research. This is what I would call the "faith-coefficient" operating in psychiatric treatment. There is an inherent risk in psychosurgery in adopting the typically "detached" attitude of the surgeon's relationship to his patients, and forgetting the therapeutic

aspects of the psychiatrist-patient relationship. Differences and results in treatment research may be due to differences in the degree of faith, that is, the amount of enthusiasm for and belief in the efficacy of the mode of treatment exhibited to the patient by either the therapist or researcher, which the therapist possesses in their modes of treatment, which in turn influences the patient and his belief in the therapeutic abilities of his therapist. One might hypothesize that the more enthusiastic the therapist is about his own modes of treatment, the more successful, in turn, such treatment will be for his patients. I think this is one of the reasons why certain therapists and researchers obtain different results in various forms of treatment than other therapists and researchers having greater skepticism for such treatment.

Consequently, the attitude toward psychosurgery and actually doing something for the patient—the process of preparation for lobotomy of both the patient and his family and other interested and significant members of his social milieu—may explain, in part, why some cases exhibited “abnormal” behavior which was “normal” before the operation, or *vice versa*. We would thus inquire of Dr. Greenblatt as to whether or not the group of patients analyzed in this study voluntarily went into psychosurgery, or were coerced, or simply disinterested. It is likely that the voluntary group would have a better outcome or reaction to psychosurgery than the involuntary groups of patients, particularly if any negativistic attitudes were displayed toward the involuntary group by the treatment staff. To some extent, such may be at least a partial explanation for the worsening of such characteristics as excessive appetite, irritability, outspokenness, and deficient insight in one of the series presented.

In summary, Dr. Greenblatt and his associates are to be congratulated in presenting a new series of dimensions of a social nature that affect the outcome of psychosurgery, an area in considerable need of further research in not only frontal lobe surgery, but every other form of psychiatric treatment. Until such factors as the “faith-coefficient” and other social and cultural dimensions are controlled or at least delineated, differential outcome in psychiatric

research of various modes of therapy will continue to persist in the psychiatric literature. These social intervening variables, therefore, are worthy of inquiry in their own right, as well as in conjunction with improving our knowledge of and skills in psychiatric treatment.

REPLY

Milton Greenblatt, M.D., (Boston, Mass.)

One of our greatest areas of ignorance has to do with the relative efficacy of various forms of treatment in similar case groups. Until definitive studies are done of the type mentioned by Jaco, we will continue to depend on inference and prejudice. Successes are being claimed in chronic cases for all types of therapy used. What we need desperately to know is the spectrum of improvement to be expected with a given therapeutic modality in relation to others; the social and psychological conditions under which the improvement is obtained; the degree to which improvement is maintained versus relapse or regression; and finally, the relative costs of the various treatment methods.

I am personally not surprised to hear that transorbital lobotomy ran ahead of chlorpromazine, electric shock treatment, insulin treatment, and custodial care. Our recent experience is relevant. We studied comparable groups of chronic schizophrenics—one group remaining in a state hospital environment and given tranquilizers, the other group transferred to an active social milieu and given the same drugs. The results indicate that improvement rates are about the same after six months in the two environments, but that patients in the active milieu are more likely to leave the hospital because of social work attention and the use of transitional facilities. The significant feature for our discussion here, however, is that tranquilizer therapy does not appear to give as good results as psychosurgery in our estimation. Unfortunately, this is based on *impression* as we have not run *concurrent* matched or randomized groups with the different modalities. But we are intrigued with Jaco's statements which support our expectations.

I cannot give a satisfactory answer to the question as to whether those who volunteered did better than those who resisted surgery, simply because we kept no systematic data on this point at the time. His criticism is well taken, however, and were we to repeat the studies, we should certainly take this into account. Many of our patients were operated without any particular bones being made about

the operation. Some, to be sure, resisted. Many were so regressed and uncommunicative that their feeling about operation was unknown. Improvements occurred in all classes of individuals, however, but with a major positive correlation in our study between a clinical picture featuring tension, agitation, or what we might call "heightened cerebral excitation" and postoperative improvement.

In recent years we have done a good deal of work on the social components in thera-

peutic management of the mentally ill and have learned to respect the importance of the social milieu or setting as a variable affecting therapeutic outcome. The informal, subtle, or implicit aspects of the environment are especially tricky to identify, but we believe they may have a profound effect on patient care and treatment.

We wish to thank Dr. Jaco for emphasizing these most important aspects of the total problem.

PAVLOVIAN CONTEMPORARY PSYCHIATRY IN THE USSR¹

KONSTANTIN M. BYKOV

LATE MEMBER OF THE ACADEMY OF SCIENCES OF THE USSR

Biology lies at the basis of modern medicine. The laws of biology are the foundation stones of the theory and practice of medicine. Man in all his complexity, as the object of medicine, should be dealt with on a humanitarian basis—psychological, sociological, *etc.*

All attempts to create a theoretical basis for medical science *only* on biology or *only* on psychology lead to a vulgar mechanistic system, and finally to an empty idealism.

Psychiatry, like every science, reflects in its development all those general premises of a scientific world outlook that prevail at a given period of history.

Before the beginning of this century, both in the field of neurology and of psychiatry, the views of the physiologists predominated, founded mostly on analytical physiology. These had been elaborated by means of vivisection, that is, by experiments with organs and tissues studied separately without any connection whatever with the higher psychic manifestations, mostly through subjective psychology, *viz.* unscientifically.

In a brief paper it is impossible to dwell at length upon the many attempts in building up new notions of the functions of the higher nervous apparatus governing the relationship between the organism and its environment. At the beginning of our century, efforts were made to found new concepts based on the correlation between psychopathology and pathological brain anatomy (Kleist, Pötzl, Meynert, Wernicke). Among Russian psychiatrists, some propagated this so-called "brain pathology," ignoring the importance of Pavlov's researches on the functions of the higher parts of the brain.

Some Russian psychiatrists, as well as those of other countries, made theoretical use of recent physiological concepts, such as those concerning integration and disin-

tegration; the founder of these concepts was the prominent English physiologist Charles Sherrington. But that theory cannot adequately be adapted to psychiatry, for Sherrington and his followers in Western Europe, as well as in America, did not take into consideration the specific characteristics of the functions of the higher divisions of the central nervous system, nor the evolution of functions in their ascending order, *i.e.* adaptability and mutability, heredity and the individual experiences acquired during the individual's life.

The teachings of the behaviorists could not adequately represent the mechanism of normal brain activity, nor its pathological conditions. Behaviorist psychology defines only the beginning and concluding links in an act. The main intermediary, the central mechanism, remains thus unavailable to scientific investigation. In Lashley's ideas one can detect, however, a vague notion about the equipotentiality of the separate parts of the brain, founded upon a rather rough method of extirpation and upon a subjective point of view.

The brilliant work of Walter Cannon on the emotions, dealing with the role of adrenalin, and the research studies on the hormones, were isolated from general questions of physiology and pathophysiology. Endocrinology having been separated from the study of the organism as a whole, led some endocrinologists and physicians to erroneous inferences about the autonomic roles of separate hormones in the activity of an organism (Selye *et al.*). Hormones when exerting their influence, in our opinion, are still dependent upon the brain apparatus common to man and the other higher animals.

In many other countries the understanding of Pavlov's psychiatry and his research on the conditional reflexes is far from correct. Nor has adequate recognition been given to Pavlov's statement that with that development of the cerebral cortex found only in man, there appeared a higher function, the second signaling system, *i.e.* the

¹ Read at the 114th annual meeting of the American Psychiatric Association, San Francisco, Calif. May 12-16, 1958. Translated by W. Horsley Gantt, M.D., VA Hospital, Perry Point, Md.

speech function—at the basis of thought and of the higher emotions. In my opinion, Pavlov laid the foundation of the materialistic [objective] understanding of psychology. The conditional reflexes, as Pavlov put it in a letter to Pierre Janet, seem to exist for all the organs and tissues. The human organism as a whole and all its parts have their representatives in the cortex of the cerebral hemispheres.

The dynamic integrity of the organism may be regarded as wholly corroborated by practical as well as experimental knowledge. Thus began the foundation of a synthetic physiology.

Permit me now to present a rather brief summary of the Pavlovian School of experimental data and after that some facts applicable to neurology and psychiatry.

Due to his extraordinary gifts of observation and experimental skill, Pavlov, as is known, discovered a new class of reflex phenomena arising in the individual's life, hitherto wholly overlooked in experimental practice, a class vast and important, embracing all the reactions of man and animals beginning with the primitive reflex reaction of salivary secretion to the signals of food, including words. Thus every reflex reaction of the brain is a complicated conditional-unconditional reflex, besides those which are formed on the basis of previously originated conditional reflexes, termed by Ivanov-Smolensky conditional-conditional reflexes. These latter may give no external manifestations, and they are revealed inter-cortically only as a kind of inner speech and those unutterable feelings which are the emotions and "obscure feelings" (Sechenov); they can be connected with the cortico-visceral reactions. The inner cortico-conditional relation is formed by coincidental stimuli in several parts of the cortex and the nearest subcortical centers. According to Pavlov, there occurs a circuit in the cortex of two simultaneously or successively stimulated foci.

At present, by means of electroencephalography, researchers in our country as well as abroad are successful in accurately localising the very area of the circuit of new reflex arcs, in studying the interaction of different points of the cortex as well as of cell groups in separate layers of the cortex and the nearest subcortical struc-

tures, including the formatio reticularis.

In the study of intercortical dynamics should be mentioned the researches of Penfield. Even more sensitive are the super-sensitive electrical responses of the viscera, revealing the exact locus of excitation and inhibition in the subcortex and cortex, as well as the interactions of the cerebral parts. Pavlov had already described the interaction of cortical foci. Thanks to micro-electronics, all these considerations and facts have now been extensively elaborated in the laboratories of Magoun and a number of European researchers (Moruzzi and others). I am hoping that the method of conditional reflexes and electrophysiologic means and devices applied to the study of the dynamics of the cortical processes, will jointly contribute to a deeper insight into the intimate workings of the cerebral nervous elements.

There is now a possibility for utilizing our experimental facts and laboratory observations in the practical work of the neurologists and psychiatrists. The intercortical dynamics in Pavlov's teaching concerning brain function is based on general nervous physiology. As I said before, the conditional reflex arc is formed in the cortex between the afferent centers and the cortical visceral representations. We are not as yet quite sure about the nature of this circuit-mechanism but it is likely to be a summation process arising from repeated stimulations of the same cortical cells and the simultaneous and successive stimulation of the executive effector cells.

When the conditional reflex is elaborated by a definite isolated stimulus, then the excitation extends from the group of cortical cells being immediately stimulated to the neighboring areas due to the irradiation of the excitatory process. During repeated tests the irradiation becomes restricted and the excitatory process is confined to a localised point of the cortex. The restriction of the irradiation-excitation may proceed differently under different conditions, but the chief role is invariably performed by another basic nervous process—the process of inhibition. All the tremendous dynamic system of the cerebral cortex is operated through the interaction of excitation and inhibition. This same interaction forms the basis for the control by the

cortex of all the functions of the living organism. The conditional reflex once formed may exist throughout the life of the organism, or it may on the contrary, disappear. And yet the connection once having taken place, does not completely disappear but is only temporarily suppressed.

Of particular and great importance is the so-called ultramaximal stimulation leading to unconditional inhibition, characteristic of all parts of the nervous system, as opposed to the types of conditional inhibition peculiar only to cortical cells. The ultramaximal or protective inhibition takes place where the stimulation exceeds the working capacity of the given cells. In pathological cells even stimuli of usual strength may evoke an ultramaximal inhibition, which is biologically important for the life of that cell.

Without biological adaptability, all the manifold and harmonious activity of a living organism in all its various interconnections with the external world would be quite impossible.

The cerebral cortex of man and higher animals has the function of reverberating circuits, *i.e.* the function of acquiring, forming, creating new relations between the organism and its environment, the function of developing new life experiences, the function of ontogenetic adaptation.

All these ties between the organism and the environment being strictly determined are secured by the analysis and simultaneous synthesis of that grandiose dynamic system of the billion-cell structure of the cortex, due to the discontinuous flow of stimulation and inhibition, their irradiation and relations of mutual induction.

During the last 20 years together with my numerous and very dear collaborators I have carried out experiments corroborating Pavlov's primary assumptions that it is the cortex that controls all the processes occurring in the human body. Experimental work to that effect, the inferences they led to, and the theoretical formulated conclusions have opened new ways for a study of the normal and pathological functions of the different parts of the nervous system, and for studying the interaction of the subtlest mechanisms of the nervous and humoral factors. We have collected exten-

sive experimental data demonstrating the dominant role of the cortical apparatuses in controlling all the main vital functions. Experimentally we tried to form conditional reflexes through exteroceptors to the activity of the internal organs and the general metabolism. Our colleagues working in clinics were able to observe in their clinical practice, the tremendous role of the cortex in various pathological conditions relating to their emergence, course and recovery. Thus we came to the concept of cortico-visceral physiology and pathology. It appeared that while the cortex affects the internal organs through exteroceptive reflexes, the internal organs of different morphological structure and functional importance, possessing receptor apparatus are themselves, in their own turn, directing signals to the cortex. Thus we managed to elaborate an interoceptor signalization to the cortex. These signals which are formed, on stimulation of mechano-thermo-chemo-osmoreceptors in the visceral receptor fields, enabled us to form interoceptive conditional and unconditional reflexes. The significance of interoceptive signals both normally and pathologically is immense, for the organism is dependent not only upon an appreciation of the external world, but also upon the signals conveyed to the regulatory apparatus, derived from an analysis of processes occurring within the organism itself.

The cortex of the cerebral hemispheres constantly faces two kinds of stimuli: those of the external and those of the internal environment. The wonderful researches on the role of the *formatio reticularis* are shedding a new light upon the tonic conditions, without which the function of such a complicated dynamic system—as that chief organ of the whole organism's structure, the brain, would hardly be possible.

We admit that Pavlov's teaching concerning the higher nervous activity and its application in psychiatry were not at once adopted by our Soviet psychiatrists. Pavlov himself spoke about it in 1934. He said then that his new ideas on the work of the higher parts of the brain would be accepted only slowly by scientists (psychiatrists and neuropathologists), and that difficulty Pavlov explained as a manifestation of some survivals of dualism—that is of

the age-old habit of separating thought from the brain, of dividing the single and integral human organism into two halves, mind and body. A gradual overcoming of that dualistic outlook contributed to a broader application of Pavlov's teaching to the sphere of psychiatry and neurology. Pavlov's theory does away with all possible dualisms, because the psychic activity is treated by him as a higher nervous activity, i.e. as some physiological work of the higher brain, which in principle precludes any contrasting of the psychic and the physiological. Consequently, Pavlov's concept is in its essence one of materialistic monism.

In connection with Pavlov's well known works on schizophrenia, Soviet psychiatrists have made many researches concerning the different forms of schizophrenia (Ivanov-Smolensky, W. P. Protopopov, E. A. Popov). Ivanov-Smolensky in studying the peculiarities of disturbances of the higher nervous activity resulting from catatonia, described two forms of catatonic stupor, one depending upon extensive, and the other upon intensive inhibition. It was he who demonstrated the differences in the higher nervous activity resulting from the catatonic and the paranoiac forms of schizophrenia in different stages of their development and under different conditions of the schizophrenic, and especially in manic-depressives.

A number of research works are devoted to the study of the nervous mechanism of epilepsy and the accompanying pathophysiological alterations of the higher nervous activity (Speransky, A. D., Serebina, and others). One should also mention a series of studies devoted to the pathophysiology of hallucinations and delirium. In our opinion, the most important for psychiatry is Pavlov's concept of "protective inhibition."

Its essence, in brief, may be reduced to the following: if the cortex is affected by some very strong stimuli, there may occur in the cortical nervous cells the so-called trans marginal or ultramaximal inhibition which preserves the cells from exhaustion and destruction. It is this property that Pavlov termed "protective inhibition." The latter may arise in the cells even in reactions to only ordinary stimuli. But they may act not as ordinary, but rather as ultra-

maximal stimuli, owing to a pathological weakening of the nervous system, such as is not infrequently observed in the first stage of the catatonic form of schizophrenia. Such protective inhibition may take place when the organism is subjected to different intoxications. It may be regarded as a physiological measure of the struggle against injurious influences. But if continued for a long time, such an inhibition may itself prove to be pathological, in which case we witness a shift from physiology to pathology.

On the basis of the concept of protective inhibition a further study of the sleep-cure, started by Pavlov, is being carried out.

Pavlov exerted a considerable influence on psychiatry by his teaching concerning the second signalling system of the cortex. One can say without exaggerating that psychic troubles as a rule result from a disturbance of the second signalling system—the system of speech and thinking. Pavlov used to say: "If you haven't got ideas, you are unable to see facts." His ideas of the second signalling system provide the basis for much new work.

Now let me say a few words about further work on Pavlov's types of nervous system—their relation to the strength of excitation and inhibition, their balance and imbalance, mobility and inertia.

When studying the higher nervous activity we systematically resort to the methods of studying conditional reflexes, EEG, and biochemistry—in particular, the analysis of vitamin metabolism in neurotics. By all these various analyses it was proven that in all the forms of neuroses there is a disorder of the internal cortical inhibition, i.e. conditional inhibition, and especially in hysteria.

These data are of vital significance for an understanding of the pathophysiological nature of neuroses in man and their treatment: 1. Treatment with the aid of the so-called (in the USSR) "protective regime," 2. Treatment by means of a protracted sleep, applying minimal doses of soporifics and hypnosis, 3. Training of the inner inhibition, 4. Psychotherapy, hypnotherapy including, 5. Treatment with medicines individually dosed and dependent upon the neurotic type and upon the nature of the disease, 6. Physiotherapy, 7. Medical

physical culture (at the Clinic of Nervous Affections—Prof. Kryshova).

Hypnosis is investigated not only as a phenomenon in itself, but it serves as a method of experimental and physiological analysis of man's higher nervous activity (Physiological Laboratory of Prof. Maiorov), as well as for an analysis of the various hypnotic phases, and the interaction between the first and the second signalling systems.

Pavlov's ideas are gaining ground in the minds of many scientists of other countries. In 1955 there was founded a Pavlovian Society in Baltimore, by Gantt and others.

We do not share Freud's theory of neuroses; it is, in our opinion, devoid of a scientific groundwork. The premise of psychic energy striving for an outlet, and the subdivision of an integrated psyche into 3 parts "Id," "Ego," "Super-Ego" are arbitrary and without scientific confirmation. The dominance of an unrecognizable unconscious in man with his inclinations and instincts is in contradiction to modern neurophysiology and the psychology of man as a social being. Even in the higher animals the acquired conditional reflexes perform an important role. Man's behavior is at the same time almost wholly determined by his social surroundings. According to Freud one of the causes for neurosis is civilisation which restricts instinctive action in man. We hold that certain social environments may be the source of neurosis, not because of restricting instincts, but due to many social contradictions.

One of the main fallacies of Freud's theory is its pansexualism. Far from denying the biologically important significance of the sexual instinct in human life as well as in the origin of several neuroses, we refuse to consider it as the most important factor either in normal life or in pathology. The source of most neuroses is not the mythical Oedipus or the discharge of the suppressed libido, but various external influences, mostly social.

The physiological mechanisms causing neuroses are thoroughly investigated by the Pavlovian school.

Freud's method of psychoanalysis applied to the study of personality is reduced to a sexual interpretation and therefore is tendentious.

The attempts of some researchers, especially in the U. S. A., to combine Freudism with Pavlovian concepts in our opinion lead to no solution whatever. Pavlov himself in general occupied a negative stand to Freud, though he made use of some of Freud's materials to illustrate his own ideas.

Modern psychosomatic medical theory, having enjoyed a particular development in the U. S. A., rests on Freudism and its psychoanalysis and pansexualism. The psychosomatic theory explains the origin of somatic diseases by psychic causes. The cortico-visceral theory also regards the disturbances in the higher nervous activity as a source of a number of somatic diseases. But notwithstanding this seeming likeness, the two theories are directly opposite, the cortico-visceral theory being based on materialistic monism. The organism is an indivisible and integral system, where the cerebral cortex is connected with the internal organs, but the organs are also closely related to their surroundings. The psychosomatic theory is a dualistic one, where the mind is divorced from the body and is only able somehow to affect the latter. The adherents of that theory consider the psychic causes of disease as the unconscious sources of actions and the instincts. Different internal, dermatological and even surgical diseases including traumatic ones, they consider as channels for escape of the unconscious psychic energy.

The psychosomatic theory is widespread in American psychiatry whereas in the USSR it has no place. This is to be explained by our different approaches. In order to attain a common scientific language we should not have to discuss terminology, but we should exert our efforts to a clear understanding of the theoretical foundations of medical science in general and in psychiatry in particular.

An important problem for physiology is collaboration with clinicians. In concluding my talk, I should like to express my desire—that there may be established a friendly working contact with American colleagues, as well as with the scientists of all countries. This would be the best guarantee of the development of that human science, viz. medicine, which strives to preserve the health and prolongation of a happy and peaceful life.

THE SIGNIFICANT VARIABLES IN PSYCHOPHARMACEUTIC RESEARCH

LEWIS J. SHERMAN, Ph.D.¹

The literature describing the effects of tranquilizing drugs has reached enormous proportions in recent years(1). Few developments in the history of psychiatry have aroused so much controversy(2) or stimulated so many investigations. Most of the early research gave an unduly optimistic picture of the drugs' efficacy because of inadequate experimental controls and inappropriate procedures(3). Recent studies have shown considerably more methodological sophistication and have placed the value of chemotherapy in proper perspective. It is no longer unusual to find several appropriate control groups, double-blind administrations with placebo, tests of statistical significance, and reliable and quantifiable behavioral measures used in many studies.

Only recently has there been a corresponding increase in our conceptual or theoretical precision to keep pace with this increase in methodological precision(4). Although current studies are now more carefully designed and executed, many significant variables that may influence the drug response still remain uninvestigated and, in some cases, unknown. Undoubtedly the main reason for this situation is the large number of variables relevant to any given problem in chemotherapy research and the difficulties involved in their management. If we intend to gain any valid knowledge of drug effects however, we cannot avoid dealing with these complex forces. By over-simplifying for the purpose of experimentation, we always run the risk of neglecting important influences that will make generalizations beyond the experimental setting impossible. Only by studying many of the important variables—and their various permutations and combinations—can we ever hope to approximate in our research endeavors the complexity of human functioning found in real life.

SIGNIFICANT VARIABLES

A person's response to medication is in-

¹ Research Psychologist, VA Hospital, Brockton, Mass.

fluenced by the interaction of 3 major classes of variables, namely, drug, situation, and person. All behavior studied in drug experiments, whether measured by rating scales, objective or projective tests, controlled observations, clinical impressions, *etc.*, is some complex function of these 3 variables operating simultaneously upon the patient. Although this conception is generally accepted at a theoretical level (4), it has been frequently ignored when undertaking specific studies. Most investigators have studied only the influence of drug variables and tacitly assumed an invariant response to its pharmacological properties by all people in all places. Fewer investigators have focused on the situation factors that bring about a particular drug effect and, most neglected of all, have been the person variables that determine the uniqueness of each individual's response to the drug. No one has yet attempted to study the effect of all 3 variables within the framework of a single investigation.

The purpose of this paper will be to discuss each of these 3 major categories of variables and to cite illustrative studies of each. An attempt will also be made to outline a methodology whereby all 3 may be investigated simultaneously to determine their joint effect.

DRUG VARIABLES

The overwhelming number of chemotherapy studies are concerned only with the effect of drug variables on behavior. Type of drug, drug combinations, dosage level, and length of administration are the usual dimensions investigated in this category. Situation or person variables are either omitted or presumably controlled by matching groups on several criteria.

In its emphasis on drug variables, the typical chemotherapy study commits the error of oversimplification by assuming that behavior can be isolated from its social context and that the patient is merely a passive recipient of a purely pharmacological agent. It assumes an invariable response

to the drug: all people reacting in the same way, regardless of the situation in which the drug is administered or the person receiving it. In those studies where no consideration is given to situational or personal factors, authors are forced to state that any improvement in behavior is attributable only to the drug. Such a conclusion has been strongly criticized by Rashkis and Smarr: "It is patently impossible to assume that improvement in patients to whom drugs have been administered is due solely to the drugs themselves"(5). However, the majority of experimenters can reach no other conclusion because of the artificial nature of their research designs.

We have to look no further than to the extremely wide variation in drug results to realize that factors other than the drug are exerting an effect. One review of 52 studies showed 34 to 100% improvement under chlorpromazine and 17 to 100% improvement under reserpine(6). Granting the methodological inadequacies of many of these studies, it is clear that the drug alone is contributing only a portion to the total effect and that other factors—equal, and in some cases more important—must be operating to influence behavior.

SITUATION VARIABLES

It has long been recognized that the psycho-social environment in which the patient resides and receives treatment has a determining effect on his behavior. The findings of Stanton and Schwartz(7) that staff harmony and discord may be reflected in patient functioning, the conclusions of Greenblatt, York, and Brown(8) that patients may improve without any formal therapy simply by being in a "therapeutic milieu," and Caudill's recent work(9) on the total hospital atmosphere all support this thesis. It is evident that patients are not treated in a vacuum and that they respond to a variety of subtle forces around them in addition to the specific therapeutic agent under investigation.

Those social forces impinging upon the patient from the research and hospital setting and those psychological influences stemming from the various personnel with whom he comes in contact are the situation

variables that must be considered in psychopharmaceutical research.²

It is necessary to specify the total social situation in which any drug experiment is carried out. No comparisons between separate studies or replications of single studies can be made without a clear description of the research context. A recent report(10) emphasizes this precaution and as a guide to such description lists 19 items, under the general headings of Hospital Structure, Hospital Personnel, and Patient Population, which may have an influence on patient response. Size, location, architectural characteristics of the hospital; number, training, description of personnel; and special characteristics of the patient population are some of the variables considered important in this regard. It is also recommended that "... any alterations in the setting introduced by the investigator or by circumstances after the study was begun" should be clearly specified because of the possible influence they may have on behavior. The importance of this latter point is documented in a study by Wing(11) which used a sociologist as ward observer. He found the observer's presence on the ward crucial enough to bring about an initial improvement in patient behavior, and this improvement was later reversed when the observer was no longer unfamiliar to the patients.

In spite of the multiplicity of significant variables operative in the social setting, only the research unit specifically has received much attention. That improvement in behavior can occur solely by being selected as a subject and by residing on a research ward has been clearly demonstrated by Rashkis and Smarr(5). Forty-eight chronic female schizophrenics were observed on a research unit for 7 months prior to the administration of drugs in order to establish a pre-drug base line. Thirty-nine of these 48 showed improvement without medication due to what the authors term a "milieu effect" and even after 7

² It is recognized that the distinction between social and psychological situation variables is artificial. For example, the psychological attitudes of ward personnel are very closely related to the social philosophy of the hospital. However, the distinction will be made for purposes of exposition and to categorize the several relevant studies concerned with these variables.

months many had not yet stabilized. This finding is an illustration of the "Hawthorne Effect" (12) originally observed in industrial settings over 20 years ago where increased attention, heightened interest, and social stimulation alone were responsible for changes in behavior.

Gerard considers these "milieu effects" of major significance and primarily responsible for the enthusiastic early reports on the effectiveness of tranquilizers:

I think it has been demonstrated sufficiently that, at least in the earlier stages of drug testing, those hospitals which were reported to get the greatest change with the introduction of tranquilizers were the ones that had almost a completely custodial attitude. Prior to the drug experiments, the patients had been pretty much neglected; now they were given attention as well as a drug (13).

A comprehensive study now under way is attempting to assess directly the influence of the total social setting on drug response (14). The cooperating hospitals are the very large acute and custodial Boston State and Metropolitan State Hospitals and the "130-bed Massachusetts Mental Health Center which is an active treatment hospital with a multi-discipline approach to therapy and rehabilitation." The specific aims of the study are to determine the differing effectiveness of drug therapy between large state hospitals and a small intensive treatment center. By transferring selected patients from one study hospital to the other, the investigators can see whether social therapy alone is superior to drug therapy alone or whether social and drug therapy together is more beneficial than either one separately.

Recently, some attention has been devoted to the second group of situation variables, *viz.*, the psychological influences stemming from personnel attitudes and feelings. Quite early in the development of the tranquilizers it was noted by the staff of the Michael Reese Hospital that they were not obtaining the same degree of improvement with drug therapy as workers in other hospitals (15). This led them to study the attitudes of their personnel toward drugs as a possible determining factor in their lower improvement rate. After an intensive qualitative analysis of the hospital setting, they con-

cluded that attitudinal factors were indeed important and that contributing to their lack of success was "... the relatively negative attitude of our hospital personnel toward the prescription of drugs as compared with alternative modes of therapy" (15).

A quantitative study by Feldman (16) on the relation of staff attitudes to treatment outcome agrees with the above findings. He found a high relationship between the attitudes toward drugs of 37 physicians and their success with the drugs. Those physicians most enthusiastic about medication and convinced of its value had by far the greatest patient improvement. One investigator, for example, who was completely sold on the merits of tranquilizers had 77% of his patients improve; another who considered drug therapy "contrary to our dynamic concepts" and a waste of time had only 10% improvement. Related findings by Thorpe and Baker (17) have shown that nurses' attitudes toward medication are also of importance and influence their judgments of patient improvement.

In view of these few, but nevertheless highly suggestive, findings that "... there is a significant relationship between the enthusiasm of the investigator and the therapeutic effect of the drugs" (1), it seems evident that more research efforts should be directed at this problem. The typical drug study, which only states that certain physicians, nurses, and aides attended the patients during the course of the study—but says nothing of their beliefs and feelings about drug therapy—seemingly ignores a relevant research variable.³

PERSON VARIABLES

The most neglected area in chemotherapy research has been the relationship between drug effects and the personality of the drug recipient, *i.e.*, the influence of person variables on behavior. While it is a truism that "people are different," apparently many in-

³ Research in this area has been facilitated by the construction of an objective scale to measure attitudes toward tranquilizing drugs by Mason and Sacks (18). Although primarily devised for use with physicians, it can be modified to apply to nurses and aides as well. Attitude scores have shown a significant correlation with actual use of drugs by physicians and are now being correlated with several measures of patient improvement.

investigators have assumed that (a) these individual differences will balance out in their experimental designs and contribute equally to all groups, or (b) that drugs exert an invariant effect regardless of the personality differences of the people receiving them. The few studies that have concerned themselves with the problem of individual differences show that neither of these assumptions is necessarily true.

The considerable literature on placebo effects (19, 20), although not usually concerned with tranquilizing drugs, nevertheless has relevance here. The several studies by Lasagna, Beecher, and von Felsinger (21, 22, 23) have all demonstrated that "the nature of the subject" is an important determinant of drug effects. It appears that there are discernible personality characteristics which account for a certain portion of the effect of any given drug. One study on the influence of morphine and a placebo on pain reduction showed that 42% reported some relief of pain following the placebo injection. From a psychological test battery, the authors were then able to characterize these "placebo reactors" in terms of some specific personality patterns (24).

Confirming these findings are the investigations of Hill (25) and Kornetsky (26) wherein objective measures of personality functioning were used. In many cases they found that personality differences brought about behavior which minimized and even went contrary to the typical physiological effect of the drug. There were indications that a "general drug sensitivity" factor exists in some people which causes them to react to all drugs. Other subjects not possessing this factor are less affected by drugs. Relatively little is currently known about the personality variables underlying these idiosyncratic reaction patterns. In summarizing his work, Kornetsky is insistent on the importance of person variables in drug research:

The effects of drugs on psychological performance in man are due not only to the specific pharmacological activity of the drug, but also to the specific reactivity of the subject and to an interaction of the two (26).

It is unfortunate that the rarest type of objective chemotherapy experiment is the one that would answer the most important

question facing the psychiatrist: Will this drug benefit this *particular* patient with his unique background, motivation for treatment, personality structure, and symptoms? The few tranquilizer studies that have investigated this problem of individual differences suggest there is a relationship between the nature of the drug recipient and his drug response. Ellsworth and Clark (27) were able to relate improvement under reserpine and chlorpromazine to a patient's variability in pre-drug "palmar sweat ratings" or generalized anxiety level. Kornetsky and Humphries (28) found high correlations between MMPI psychasthenia and depression scores and their patients' subjective and objective behavior changes following the administration of several drugs. Finally, Kelly *et al.* (29) correlated 68 individual personality variables with the behavioral effects of meprobamate and prochlorperazine. Although many of the significant correlations obtained may be due to chance because of the enormous number tested, the investigators still feel that, "Each significant correlation has interest as a potentially fruitful hypothesis for future experimentation" (29).

The final group of studies investigating the determining role of personality are those conducted within a dynamic or psychoanalytic framework. They attempt to explain the divergent chemotherapy results in terms of the individual's psychological perception of the drug and what medication means to him. Epitomizing this approach is the comment by Fernandes that

the effect of the (tranquilizing) drug upon the whole personality is salutary or detrimental, according to the way it is experienced by the patient's ego, and the way it is elaborated and valued by the patient himself (30).

Sarwer-Foner, in a series of related investigations, has similarly emphasized that

The therapeutic effect (of drugs) . . . is due not to the pharmacological action alone, but to the way in which this physiological action psychologically influences the patient's defenses in terms of the patient's total situation (31).

In the course of evaluating 5 different tranquilizers, Sarwer-Foner found clear-cut untoward reactions in about 17% of his

cases. These patients, instead of showing behavioral improvement, developed panic and paranoid reactions, agitation, increased withdrawal, and enhanced anxiety. He offers as hypotheses for these negative reactions the psychological meaning the patient attributed to the physiological effect of the drug. For example, those patients who typically use motor activity as the main defense against unconscious passivity may become threatened and anxious by the drug's restraining action. Similarly, those patients with strong latent homosexual conflicts may interpret the administration of the drug as "an unwelcome assault or seduction" and react adversely to the chemotherapy. Although these studies have been criticized by Bennett(32) for their methodological shortcomings, they stand as significant exploratory works which can furnish hypotheses for more precise experimentation. There is too little known about the relevant personality variables operating in the psychopharmaceutical situation to discount any possible sources of influence in our research designs.

FACTORIAL DESIGN

It has been shown that a patient's response to medication is influenced by the interaction of drug, person, and situation variables. Changes in behavior are due not only to the type and quantity of drug administered but also to the total social setting in which treatment occurs, the feelings and attitudes of personnel attending the patient, and the personality structure of the drug recipient. Studies which investigate only one or two of these influences can furnish only partial answers to our research questions. It is clear that what is needed is a research design that will permit the simultaneous study of several of these variables in a single experiment.

Such a procedure is called a factorial design.⁴ "A factorial design is one in which we have two or more variables each varied in two or more ways and studied in all

possible combinations"(33). In contrast to the traditional approach of holding all but one variable constant, in a factorial design the experimenter deliberately varies as many factors as he is interested in studying. This procedure is more comprehensive than other methods because interactions between variables as well as the main effect of each variable may then be studied. It is also more economical because a wide range of conditions are sampled using fewer subjects and observations than would be required in conducting separate studies for each factor.

In brief, a factorial design can answer more than one question in a single experiment. It can tell us not only that one drug is superior to another, but also under which treatment conditions and for which types of patients this superiority obtains. This latter information is of primary importance in drug experimentation. Edwards and Cronbach stress the necessity of going beyond a simple "A better than B" approach in evaluative research:

It seems obvious at this point that simple comparisons of (Drug A and Drug B) may often be relatively worthless, and that comparisons gain value as the design isolates the specific types of persons and situations for which A is superior(33).

A single factorial experiment could study the relative effect of each of the 3 major classes of variables outlined in this paper. For example, we could investigate within the framework of a single study the changes in behavior produced by Drugs A and B (drug variables) in chronic and acute schizophrenics (person variables) when treatment occurs in custodial and rehabilitative hospitals (situation variables). The several questions asked in this research are each answered by an analysis of all the possible main and interaction effects.⁵ From the wealth of information that could possibly be obtained from

⁴ An excellent account of the research possibilities of factorial design is contained in the article by Edwards and Cronbach(33). Although concerned specifically with psychotherapy research, it is also applicable to chemotherapy research. More technical discussions may be found in McNemar(34), Kogan(35), and Edwards(36).

⁵ Main effects are the ones that occur consistently regardless of variation in any other experimental factors. For example, one drug may be superior to the other irrespective of the types of patients or the hospital setting. Interaction effects are the ones due to a combination of two or more experimental factors. For example, one drug may be superior to the other only when administered to particular types of patients or only when given in a particular hospital setting.

such a study, the basic advantage of a factorial approach is clear: *the more variables systematically investigated, the more comprehensive the information obtained.*

In view of the considerable evidence that changes in behavior are not merely a function of the drug itself, it is surprising that so many studies still neglect or attempt to hold constant all other relevant variables. Instead of excluding these non-drug sources of influence, we should recognize their existence and, by using a factorial approach, actually build them into our research designs. Only in this way can the combined influence on behavior of drug, situation, and person variables ever be ascertained and more valid knowledge of drug effects obtained.

SUMMARY

This paper has reviewed selected studies that indicate the importance of situational and personal factors on a patient's response to drug therapy. A factorial research design has been proposed as the appropriate means of evaluating several of these significant variables in a single experimental study.

HELLER'S DISEASE AND CHILDHOOD SCHIZOPHRENIA

NATHAN MALAMUD, M.D.¹

The problem of differentiating psychogenic from organic symptoms is often a challenging one, and this applies in particular to the field of child psychiatry. In discussing the severe personality deviations of pre-school children, under the title of "atypical development," Rank(1) stated:

By this term we refer to those severe disturbances in early development which have been variously diagnosed as Heller's disease, childhood psychosis, childhood schizophrenia, autism, or mental defect.

Such indiscriminate grouping of etiologically different conditions can however be misleading both for theoretical and practical reasons.

Since so-called Heller's disease is most apt to be confused with childhood schizophrenia, it is proposed here to delineate the former condition and to illustrate the problem of differential diagnosis from schizophrenia through a clinicopathologic analysis of a series of cases.

Under the designation of dementia infantilis, Theodor Heller(2) described a disorder in 28 children whom he observed and followed between 1905 and 1930. According to Heller, these are children who, without preceding illness, become conspicuous in their third or fourth year of life through symptoms of a character disorder. Whereas they have been placid or lively by nature until that time, they become moody, negativistic, disobedient, often raging without reason, or whining. They tend to be destructive, and many show anxiety states, occasionally of an hallucinatory character. Following these initial symptoms, they rapidly undergo a process of mental regression which leads within a few months to a complete loss of speech and to apparent idiocy. During the regressive period, motor disturbances frequently become evident. The children acquire tic-like movements, they grimace and pose in peculiar positions. Many become inconti-

nent of urine and sometimes also of feces. It becomes necessary to feed them. During all of this, there remains a certain degree of attentiveness, yet they are unresponsive to any approach through remedial education.

Heller was of the opinion that this condition did not belong to the group of schizophrenias. However, according to Kanner(3), it was customary to list Heller's disease among the varieties of infantile schizophrenia until Corberi found in brain biopsies performed on 4 such patients "diffuse lipoid degeneration of the ganglion cells." These findings led to the assumption that the condition represented a cerebral degenerative process akin to Tay Sachs' disease. Since, however, blindness was not a feature of the disorder, it suggested a process similar to that described by Kufs and by Walter as "amaurotic idiocy without amaurosis." Kanner could find no case reports of Heller's disease in the American literature and stated:

I have seen only three unequivocal cases. In one it was possible to obtain specimens of brain tissue through a biopsy done in Dr. Walter Dandy's department. Evidence of widespread cell degeneration, especially in two layers of the cortex, was unmistakable.

He also refers to reports by Kennedy and Hill, and by Jancke, of Heller's disease following pertussis. Kanner emphasized the essentially organic basis of Heller's disease as distinct from the condition of infantile autism which he first described and which he regarded as fundamentally schizophrenic in nature.

CASE REPORTS

The cases to be described consisted of 3 separate pairs of siblings and are therefore considered below under their respective family names.

Family R.—Lynn, a 15-year-old girl, developed normally until the age of 3 years when she began to exhibit increasing difficulty in walking and irregular twisting movements

¹ Neuropathologist, The Langley Porter Neuropsychiatric Institute, San Francisco, Calif.

of the arms and body. At the age of 6, her speech became slow and indistinct. When she started school, she became a behaviour problem. For example, she would go to the boys' toilet and expose herself, would tell many fantastic tales and her school work was poor.

At the age of 10, she was examined in a pediatric outpatient clinic, at which time she exhibited flight of ideas and inappropriate emotional reactions. There were mild neurologic signs consisting of dysarthria, choreo-athetoid movements of the hands and arms, ataxia on finger to nose and heel to knee tests, a somewhat unsteady broad-based gait, hyperactive deep reflexes and questionable pallor of the temporal half of the left disc. An EEG showed evidence of generalized dysrhythmia. Laboratory tests, including examination of the spinal fluid, were negative. A diagnosis of mild athetoid form of cerebral palsy was made but, because of the prominence of the psychiatric features, she was admitted for further observation to the psychiatric clinic where she remained for approximately a year.

In the hospital, the patient was first described as dishevelled in appearance, preoccupied, varying in mood between unmotivated, mirthless laughter and apparent sadness, and incoherent in her conversation. She appeared to respond to auditory and visual hallucinations, for example she talked about seeing little objects walking around in the air. It was difficult to test her sensorium. Her behaviour was erratic, impulsive and often violent. Psychologic tests led to the conclusion by the psychologist that "from the nature and severity of this girl's personality disturbance, it seems possible that this factor alone could account for the disturbed intellectual functioning." The psychiatrist felt that there were sufficient psychogenic factors in the girl's environment, such as parental discord, to account for an emotional disturbance, quite apart from any organic factors. The final diagnoses were juvenile schizophrenia and athetoid form of cerebral palsy. During the course of her hospitalization, the patient was said to improve inasmuch as she became less destructive, and appeared more responsive. She was taken out of the hospital against advice and remained at home. Her further course was one of steady decline, so that in the last 2 years of her life, she became completely unable to walk or talk. Death occurred at the age of 15.

Roger, younger brother of Lynn, now aged 14 years, was said to be well until about the age of 12, when he began showing tremor of his hands and personality changes. From a quiet good student he became very talkative,

neglectful of his personal appearance and failing in his school work. More recently he has been hallucinating, believing that termites were crawling in his bed and complaining that people were persecuting him and going to hang him. He was afraid to leave his mother's side even for a moment and preferred to remain alone and daydream.

Examination in the pediatric clinic revealed nystagmus, ataxia and athetosis. On the Wechsler-Intelligence scale for children he was awarded a full scale I.Q. of 68 but the psychologist remarked that "the record was not unlike that of a schizophrenic process-confused, perseverative and evidencing residual learning." The results of the Bender-Gestalt test also suggested a psychosis. An EEG was considered as moderately abnormal. Laboratory tests, including examination of the spinal fluid, were negative.

When last seen, the patient was showing signs of further deterioration.

Family E.—Marilyn, a 7-year-old girl had a normal birth and early development. At the age of 3 years, she was said to have been frightened at a Halloween party. The next day she appeared fearful and began nocturnal screaming, which continued unabated for the next 6 weeks. She gradually became more seclusive, negativistic and mute, was unable to adjust in kindergarten, and later developed incontinence of urine and feces. At the age of 5, she was examined in the pediatric clinic. Physical examination was negative and there was no mention of any neurologic abnormalities. The psychologist described her as showing "essentially marked instability in her emotional reactions, varying between lethargy, unmotivated laughing and crying, and between mutism and outbursts of unintelligible words and songs." She was awarded an I.Q. of 33, on the Kuhlmann-Stanford and of 47 on the social maturity test and was committed to a hospital for the mentally retarded where she continued to deteriorate until her death at the age of 7.

JoAnn, younger sister of Marilyn, developed normally until the age of 5, when she began to exhibit awkwardness, speech defect, spells of trembling and retardation in her school work. When examined in the pediatric clinic at the age of 7, she showed ataxia, dysarthria, mental regression and EEG evidence of paroxysmal dysrhythmia. She continued to deteriorate and, by the age of 9, her I.Q. was estimated at 55 and a few months later at 30. The further outcome of her case is at present unknown.

POSTMORTEM FINDINGS

The significant pathologic findings in the two patients who died were limited to the central nervous system. In each case there was widespread disease of the neurons, from the cerebral cortex to the spinal cord. The changes consisted of ballooning of the nerve cells, their dendrites and axons, as a result of deposits of a lipid material. This consisted of granules which stained poorly with the scarlet red method for neutral fat but positively with the Nile blue sulfate method, for fatty acids and other more complex lipids. (Fig. 1a, b, c, d.)

COMMENT

It was obvious that the diagnosis in the above cases was amaurotic family idiocy. In the absence of amaurosis it appeared to be a form of the disease, previously referred to as "amaurotic idiocy without amaurosis." Its onset at the age of 3 years in the two cases that died suggested the Bielschowsky-Jansky or late infantile form of the cerebral lipoidoses. In the experience of the author, such cases are not uncommon, but in the absence of the specific retinal findings, are often misdiagnosed. It is noteworthy that in the still living siblings the correct diagnosis was made only after the autopsy in the two patients who died revealed the true nature of the disease.

Family M.—Sharon, a 13-year-old girl, had a normal birth and early development. When she started school at the age of 6, it was noted that she was slow in comprehension, repeated grades and had to be placed in a special class. At the age of 8, her behaviour became bizarre and impulsive, and she was observed to have "blank spells." When examined at a local hospital, an I.Q. of 62 was determined and diagnoses of mental deficiency and petit mal epilepsy were considered. At the age of 11 she was hospitalized for a year in a children's psychiatric clinic. Some of the examiners characterized her behaviour as autistic with diminished speech, punctuated by irrelevant and bizarre responses, mannerisms, and sudden shifts of mood from fearfulness to apathy. Others described her speech as dysarthric and her movements as choreiform. The psychologist concluded that she was showing "classical schizophrenic signs with perseveration of movement, speech and ideation, tics, grimaces and mannerisms, clinging physically to adults with increased motility and reduced verbaliza-

tion." An EEG disclosed a slow disorganized record with evidence of generalized paroxysmal dysrhythmia. Her final diagnosis was established as childhood schizophrenia with catatonic features. She continued to deteriorate and was transferred to a State hospital for the mentally retarded where her condition was diagnosed as degenerative chorea. She died there at the age of 13 years.

Ronald, aged 11 years, younger brother of Sharon, developed normally until about the age of 5-6 years. When he started school, he did poorly, was considered emotionally disturbed, requiring placement in a special class. At the age of 8, he was referred to a mental hygiene clinic. There, he was described as hyperactive, fearful, having a short attention span and his I.Q. was determined at 54. He was diagnosed as mental deficiency with schizophrenic reactions. At the age of 10 he was admitted to the same psychiatric clinic as his sister. Like her, he was variously described as excitable, confused and erratic or as undergoing abrupt involuntary choreoathetoid movements. The psychologist felt that "the patient demonstrated signs of deterioration which were either on a schizophrenic or organic basis." The patient was committed to a State hospital where his EEG was described as a slow, disorganized record with a spike and wave activity suggestive of convulsive susceptibility. He died there at the age of 11 years.

POSTMORTEM FINDINGS

The pathologic findings in the two siblings of Family M. disclosed changes in the brain of an unusual type and location. They were degenerative lesions that involved symmetrically and severely the corpus Luysi and to a lesser degree the mammillary body and the mammillo-thalamic tract. In these areas, the neurons and their nerve fibers had virtually disappeared, leaving only a few shrunken nerve cells and fibers behind, accompanied by a dense reactive fibrillary gliosis. (Fig. 2a, b, c, d.)

COMMENT

The lesions in the two cases bore the stamp of a primary degenerative disease because of their absolute restriction to these two nuclear masses and because of their symmetry. This was further confirmed by the identity of the changes in the two siblings indicating the hereditary basis of the disorder. In the experience of the writer, such a disease with pathoanatomic

and organic brain pathology, as presented in the literature from the standpoint of the clinical picture. It is reasonable to assume that the similarity of the clinical picture of the two types of disease could be attributed to the focus in the organic focus. But as is well known, the nucleus is a large part of the extrapyramidal system, disease of which has often been associated with such disturbances of movement as *hysteria*. Whether the hyperkinesia in these two children was one of *hysteria* or *chorea* remains undetermined perhaps because attention was focused on the psychiatric picture and as a result the neurologic status was not carefully evaluated. The clinical manifestations of the lesions in the mammillary bodies are not *hysteria*. However, these may be compared with such other disorders in which the mammillary bodies are primarily affected as for example Korsakoff's syndrome. In all such instances it is possible that disturbances in emotional expression and other psychic functions can be attributed to a disruption in the connections of the limbic system of which the mammillary bodies form a link.

DISCUSSION

The cases reported above illustrate several types of organic brain disease occurring in childhood, in which the clinical manifestations were those of progressive psychologic and neurologic deterioration. As such they closely resembled the cases described by Heller, even though such a diagnosis was not actually made. It is apparent, however, both from the present cases and others from the literature that the designation of Heller's disease is not sufficiently precise, can in fact be misleading and therefore should be abandoned. For not only has it become a waste basket diagnosis for all sorts of organic brain disease but, more important, it has been confused with childhood schizophrenia.

In agreement with Kanner, the aim in diagnosis should be to distinguish between disease entities along etiologic lines. In our cases, the familial occurrence and the post-mortem findings clearly established the hereditary metabolic or degenerative nature of the disease in each of the cases. However, the familial trends and the precise

diagnosis were not established, and yet the children's findings were determined on the basis of a part of the picture.

Regarding the diagnosis of *childhood schizophrenia* one appeared to have been made by either ignoring or undervaluing the role of the organic factors in the total picture. For example, the motor disturbances, such as the choreiform movements, were considered to be tics or mannerisms, and the abnormal EEG findings were not taken into consideration. Instead, the emotional and behavioural disturbances became the focal points of interest. Even when the organic factors were recognized it was felt that the personality disturbances were on a different basis. Their etiology was searched for and discovered in certain traumatizing environmental or psychogenic factors. In the opinion of the writer it does not appear that there was sufficient proof for the latter contention. Rather, the "schizophrenic" symptoms in the cases seemed to be directly related to the brain damage. As already stated previously, Kanner was convinced of such an interpretation of the syndrome of Heller's disease. It should be emphasized that the term *schizophrenia*, when applied to such cases as are here discussed, is misleading since it fails to recognize the specific metabolic nature of the disease in question and consequently directs interpretation of the condition and treatment in a wrong direction.

SUMMARY

1. Six cases of children with organic brain disease, which were clinically diagnosed as childhood schizophrenia, are analyzed clinicopathologically.

2. The diagnosis of Heller's disease or of childhood schizophrenia, often made under such circumstances, is considered respectively inadequate and misleading.

THE ADMINISTRATION OF BAS, 5-HTP, AND MARSILID TO SCHIZOPHRENIC PATIENTS

AARON FELDSTEIN, HARRY FREEMAN, JUSTIN M. HOPE,
IRIS M. DIBNER AND HUDSON HOAGLAND¹

Woolley and Shaw(1, 2) first proposed early in 1954 that a deficiency or excess of serotonin in the brain might be a cause of schizophrenia. To test the hypothesis, Woolley(3, 4) suggested that 5-hydroxytryptophane (5-HTP) the precursor of serotonin, be administered to schizophrenic patients. If serotonin had no relationship to schizophrenia, then the patients should not react. On the other hand, if the disease were caused by a deficiency of serotonin, then 5-HTP should have a therapeutic effect and if the disease were caused by an excess of serotonin, then 5-HTP should intensify the schizophrenic symptoms. 5-HTP was suggested rather than serotonin itself since serotonin does not readily cross the blood-brain barrier, whereas 5-HTP does. We wish to report on the clinical and biochemical effects of 5-HTP administered to 5 chronic schizophrenic patients. At Woolley's suggestion, 1-benzyl-2, 5-dimethylserotonin (BAS) was preadministered in order to protect the patient against the gastrointestinal effects of excess serotonin (4). Two of the patients received Marsilid in addition to the BAS and 5-HTP to inhibit the presumed monoamine oxidase destruction of brain serotonin.²

In the first study, 4 male chronic schizophrenic patients were selected from the research ward of the Worcester State Hospital. The first week served as a control period. During the second and third weeks, each of the patients received orally two 50 mg. tablets of BAS daily. During the fourth and fifth weeks the administration of BAS was continued and the patients

received in addition an intramuscular injection of 15 mg. of 5-HTP twice daily. The sixth week served as a control period.

In the second study, using the same patients but one, the dose of 5-HTP was increased from 30 to 100 mg. a day. One of the patients (BER), was dropped and another male patient (YAN) substituted. The first week served as a control period. During the second, third, fourth and fifth weeks, 50 mg. tablets of BAS were given orally twice daily to each patient. Two of the patients (CAR and AKE) in addition to the BAS received 50 mg. of 5-HTP twice daily, throughout the third, fourth and fifth weeks. The other two patients (BEN and YAN) in addition to the BAS received 50 mg. of 5-HTP, i.m. and 50 mg. of Marsilid, orally, twice daily, throughout the third, fourth and fifth weeks. The sixth week of the study served as a control.

The schizophrenic patients showed no change in behavior; the psychiatric clinical picture was completely negative in all 5 patients. BAS alone, BAS combined with 5-HTP, and BAS and 5-HTP in conjunction with Marsilid were of no therapeutic value. Rudy and coworkers(5) studied 24 moderately disturbed psychotic females; they reported that BAS exerted predominantly a tranquilizing action and that 20 of the patients improved at maximum dose. Woolley (4) reported on 12 schizophrenic patients that had been treated with combined BAS and 5-HTP: he noted that only 3 of them showed an immediate improvement, but this was not sustained. He concluded that this treatment did not alleviate the disease. Our findings agree with those of Woolley.

The administration of Marsilid which may be expected to increase the brain serotonin levels over that expected from the use of BAS and 5-HTP failed to alter the negative clinical picture. While only 5 chronic cases are represented in this study the evidence casts doubt on the hypothesis that too little or too much serotonin *per se* is causally related to schizophrenia.

² This work was aided by a Ford Foundation grant and by a grant from the Scottish Rite Committee for Research on Dementia Praecox. We wish to thank Mr. Roland Laferty for technical assistance. We also wish to thank D. W. Woolley for supplying BAS and 5-HTP, and the Hoffmann-LaRoche Company for supplies of Marsilid.

Urines were collected systematically throughout the studies at about 10 A.M. after discarding the waking samples. The urines were analyzed for 5-hydroxyindoleacetic acid (5-HIAA) by the colorimetric method of Udenfriend(6) and chromatographed in a two-dimensional system(7), spotting 200 ul. of urine and spraying with Udenfriend's reagent to detect 5-hydroxyindoles and with Ehrlich's reagent to detect other indoles.

The expected increase in urinary excretion of 5-HIAA following the administration of BAS and 5-HTP combined was not observed even at a dosage of 100 mg./day of 5-HTP for 3 weeks (Table 1). Only one of the patients (BER) showed an increase and this accounted for only 40% of the 30 mg. of DL-5-HTP injected (calculated on the basis of the L-form only). The administration of BAS by itself caused no change in the urinary 5-HIAA excretion pattern of the schizophrenic patients. There are two possible explanations for these facts: 1. That schizophrenic patients lack one or more of the necessary enzymes to convert 5-HTP to 5-HIAA and 2. That BAS alone causes a metabolic block. We have presented evidence(8) that the urinary levels of 5-HIAA and the blood levels of serotonin are not significantly different in schizophrenic patients and normal subjects, which would suggest that the enzymes necessary for the conversion of 5-HTP to 5-HIAA are present and operative in schizophrenic patients as well as in normal subjects. It may be concluded that BAS blocks the conversion of 5-HTP to 5-HIAA. The fact that BAS and Marsilid prevented the formation of 5-HIAA from 5-HTP is not surprising

since Marsilid is an inhibitor of monoamine oxidase.

The paper chromatograms clearly showed the presence of the 3 major 5-hydroxyindoles, 5-HIAA, serotonin, and 5-HTP after the administration of 5-HTP to the schizophrenic patients pretreated with BAS. The spots due to serotonin and 5-HTP were not observed in the control period or after the administration of BAS alone. The accumulation of serotonin in the urine strongly suggests that BAS is a monoamine oxidase inhibitor. This is consistent with the findings of Woolley and Edelman(9) that mice treated with BAS showed no increase in urinary 5-HIAA, but that urinary serotonin was markedly increased. It is interesting to note that although both BAS and Marsilid are monoamine oxidase inhibitors, BAS acts as a tranquilizer and Marsilid acts as a psychoenergizer. This suggests that the energizing property of Marsilid may not be a function of its ability to inhibit monoamine oxidase. The accumulation of 5-HTP in the urine may be due to the specificity of the decarboxylase for the L-form with the resultant accumulation of the D-form. The Marsilid and non-Marsilid chromatograms were qualitatively the same with respect to the 5-hydroxyindoles.

An antidiuretic effect was observed in only 2 patients (CAR and BEN), (Table 1) after the administration of 30 mg./day but not after 100 mg./day of 5-HTP. There was as a result a concomitant increase in the concentration of 5-HIAA; the output of 5-HIAA when calculated on a time basis however showed no change due to administered 5-HTP in these 2 patients.

TABLE 1

THE URINARY EXCRETION OF 5-HIAA AFTER INTRAMUSCULAR ADMINISTRATION OF 5-HTP TO MALE CHRONIC SCHIZOPHRENIC PATIENTS PRETREATED WITH 100 MG./DAY OF BAS ADMINISTERED ORALLY

Patient	Administered 5-HTP (mg./day)	Output of 5-HIAA (μg./ml.)			Output of 5-HIAA (μg. hr.)			Output of Urine (ml. hr.)		
		BAS Alone	5-HTP + BAS	Effect ^b of 5-HTP	BAS Alone	5-HTP + BAS	Effect of 5-HTP	BAS Alone	5-HTP + BAS	Effect ^b of 5-HTP
BER	30	8.8	24.6	inc.	162	435	inc.	18.1	21.5	—
CAR	30	8.8	13.4	inc.	638	584	—	77.0	26.8	dec.
	100	5.6	9.5	—	412	462	—	78.3	63.8	—
AKE	30	8.0	7.4	—	420	533	—	68.5	75.1	—
	100	4.2	9.2	—	454	338	—	92.2	41.7	—

	100 ^a	6.5	10.4	—	192	200	—	34.7	20.4	—
YAN	100 ^a	4.0	5.5	—	309	512	—	77.2	59.6	—

^a In addition to 100 mg./day of BAS and 100 mg./day of 5-HTP, these patients received 100 mg./day of Marsilid
^b Where an increase or decrease is indicated, statistical analysis indicates $P < .01$.

FIG. 1

Ballooning of neurons of (a) corpus Luysi, Nissl stain x 105 and (b) anterior horn cells of spinal cord, Nissl stain x 345, Case L.R. (c) Same changes in paraventricular nucleus, Nissl stain x 105 and (d) deposits within the neurons of granular lipid material staining deep blue with Nile blue sulfate method x 475; Case M.E.

FIG. 2 A AND B

Chronic degeneration as evidenced in (a) by gliosis of corpus Luysi (C.L.) and mammillo-thalamic tract (M.T.), Holzer stain $\times 10$ and in (b) by paucity of neurons and reactive proliferation of glial elements in the corpus Luysi, Nissl stain $\times 100$: Case of R.M.

FIG. 2 C AND D

Chronic degeneration, characterized by disappearance of neurons from the medial mammillary nucleus (MM) by contrast with normal appearance of lateral mammillary nucleus (ML) in (c) Nissl stain x 21 and (d) Nissl stain x 110; Case of S.M.

SUMMARY

The administration to 5 chronic schizophrenic patients of BAS alone, of BAS and 5-HTP combined, and of BAS and 5-HTP in conjunction with Marsilid was not therapeutically useful. The fact that the patients did not react to the presumed increase in brain serotonin casts doubt upon the hypothesis that too little or too much serotonin is causally related to schizophrenia.

BAS appears to be a monoamine oxidase inhibitor. The conversion of 5-HTP to 5-HIAA was thus prevented resulting in an accumulation of serotonin in urine.

THE ROLE OF PREFRONTAL LOBE SURGERY AS A MEANS OF ERADICATING INTRACTABLE ANXIETY

JONATHAN SLOCUM, M.D.,¹ C. L. BENNETT, M.D.,¹ AND
J. LAWRENCE POOL, M.D.²

Let us establish promptly the fact that this study, in contradistinction to most reports on the results of psychosurgery in literally hundreds of patients, concerns itself with the selection, and post-operative results obtained in only 18 patients. However, they are 18 consecutive patients, spread over a period of 10 years and painstakingly selected because their presenting symptoms, their underlying personality traits and their intense degree of intrapsychic distress made us all feel that prefrontal surgery had an excellent chance of success. In no case was surgery decided upon as a "last resort" procedure, nor was it used in any of these patients simply to make them easier to take care of and less of a nursing problem. In the selection of patients for surgery the diagnostic classification was largely ignored and this small group includes nearly every non-organic category except mental deficiency and psychopathy.

The common denominator in all members of this group and the sole reason for surgery, was the presence of severe, long-standing anxiety and agitation, repeatedly resistant to the usual therapeutic approaches and disabling to the point that the patients could no longer carry on their business, marital or social existence. Five of our 18 were patients who had been obviously psychotic and had been hospitalized for many years prior to surgery. They were operated for the same intensely distressful symptoms as the non-psychotic group. All 5 are still hospital residents but the emotionally unbearable tensions for which surgery was done, have been removed in 3 and alleviated in 2. Of the 13 patients who managed to maintain their grip on reality in spite of such disabling factors as uncontrollable gross tremors, intense insomnia

and recourse to heavy barbiturate and alcohol dosage, 12 have left the hospital and have been able to resume their normal existence with no further hospitalization or treatment indicated, for periods ranging from 6 months to 8 years, with the post-operative followup averaging 4 years.

This series of consecutive cases is taken from the files of a small, private mental hospital where maximum individual attention can be given to each case. The patient census is seldom over 40, and with 3 full-time psychiatrists, it is obvious that one will have the great advantage of scores of hours spent at individual interviews. It is believed that the success of this series has been largely due to the resultant careful selection of candidates for surgery and a clear aim established for each one prior to operation. The ability to concentrate on the evaluation and investigation of an individual patient has caused us to decide against surgery in at least 50 patients initially considered for it during the years that this group was selected. In the evaluation of each case the only factors considered in the initial decision are the degree of anxiety and its duration. The history usually shows that this has been present for several years and under ordinary circumstances has been attacked vigorously by various means. Frequently the patients have become dependent upon barbiturates or alcohol in an attempt to alleviate their suffering. Usually large amounts of these agents have produced only slight diminution in their symptoms. In our group of 18, all were treated with ECT either prior to admission, or by ourselves, or both, but it has been our experience that even those reactions primarily characterized by depression will gradually build up a threshold of resistance to repeated series of ECT, while those patients who possess a considerable component of anxiety and agitation tend to do poorly with ECT from the start.

¹ Respectively, Physician in Charge and Medical Director, Craig House, Beacon, N. Y.

² Director, Service of Neuro-Surgery, The Neurological Inst., N. Y.

It must be emphasized that the decision to utilize frontal lobe surgery was reached in every case only after we became convinced that other forms of treatment had failed. The tabulation of individual patients shows that the duration of study and continuous treatment leading up to surgery averaged 14 months, not including the psychotic, chronically hospitalized group. All of them had received adequate electroshock without permanent benefit; some had received entirely too much, considering its repeatedly demonstrated inability to control anxiety in each particular case. All were the recipients of literally scores of hours spent in supportive therapeutic sessions, often during periods of persistent insomnia in the hours after midnight if it appeared that a therapeutic "break-through" could be hoped for at such a time. All were at the same time subject to physiotherapy, hydrotherapy, occupational and planned recreational therapy as well as the usual battery of drugs, both tranquilizing and directly sedative. In the majority of the non-psychotic group we also utilized an average of 8-10 lengthy interviews at night under intravenous amytal, not only to promote abreaction and subsequent sleep but to help in uncovering any strongly hostile, paranoid or antisocial *anlage* that would militate against the use of surgery, due to its tendency to release temporary aggression. If all of these approaches resulted in no consistent relief for the patient and all of the exploratory probing with Rorschach, TAT, Bellevue-Wechsler, amytal and daily clinical contact turned up no serious contraindication, we still set up one last hurdle to overcome before discussing surgical therapy with the patient or relatives. In recognition of the fact that surgery constitutes an irreversible approach to this problem, and to guard against our own increasing enthusiasm because of some very favorable early results, we decided in 1952 to request independent consultation from a source unconnected with Craig House to interview and study the patient separately, arrive at a decision for or against surgery before group conference with us. For maximum benefit to the patient, the consultant should preferably be one whose background, training

and discipline would probably influence him away from surgery. We asked Dr. Lawrence Kubie to consult with us under the above circumstances and he has examined many of the patients since 1952 that are included in this study. Several others do not appear here because we did not always reach unanimous agreement and they were not operated. This process of elimination was our last self-imposed road block in trying to avoid error in selection of candidates and it probably represents one of the main reasons why almost 95% of our small, non-psychotic group have returned home to a normal life and stayed there, the first ones operated now having remained out of hospital 6, 7 and 8 years without the necessity of further therapy.

Throughout the 20 years since Moniz first reported his work in 1936, the one consistent result of frontal lobe surgery seems to have been the reduction or relief of intra-psychic tension. For the most part, lobotomies of whatever depth or extent have been directed at the amelioration of the severely disturbed behavior of the advanced schizophrenic, with the relief of tension largely an interesting but incidental minor note. However, for our purposes it is the most important result of what is now a very modified, less extensive procedure, because in all of these 18 patients the sole aim of surgery was to give the patient relief from severely disabling anxiety and break up the concomitant tension. A 60-year-old man, hospitalized for the first time, who has had only 6 hours sleep in a week, sitting slumped in a chair with his teeth constantly chattering, muscles twitching and eyes dilated, totally unable to concentrate, is just as disabled as a hebephrenic praecox who doesn't even know you are in the room. In fact, he is even more pitiable because only 6 months ago he was an active vice president in a large investment house in New York. He still has the intellectual potential but now the selection of a necktie presents an insoluble problem and he can only pace the room with pointless activity and chattering teeth. Repeated series of ECT, Thorazine and barbiturates couldn't touch him, intravenous amytal at night would give 45 minutes anesthesia, to be followed by re-

sumption of panic. Another male patient, age 46, and with 20 years successful business life behind him, locks himself in his stateroom and slides the key under the door to his wife during a cruise because when on deck there is an uncontrollable impulse to jump overboard. He comes to us after years of repeated hospitalizations, ECT, and insulin coma, and his "solution" for the control of the intense compulsive-obsessive neurosis has been to hole up in various small hotels away from home, to drink himself into an anesthetic state alone for days on end with complete loss of self-respect. These are the types of problems that constitute this list of patients. After a variable number of months or years in spite of all efforts of their own and their physicians, they have arrived at an impasse in which they are chronically miserable, no longer able to support themselves, manage a home or even live up to ordinary daily responsibilities. The referring physician has done his best to maintain an attitude of optimism but he has "tried everything," and eventually recommends another hospitalization and probably more electroshock because he is well aware that the patient's gradual disintegration of personality, coupled with a growing aura of quiet desperation, has all the necessary ingredients for self-destruction. All of these patients in the Acute Group, without exception, had very seriously considered suicide at some point in the progress of their illness as the only remaining escape from the torment of uncontrollable anxiety, agitation and fear. The possibility that surgery might offer a reasonable and safe solution of this dilemma almost never occurred to the harassed referring physician for the simple reason that the great majority of physicians, including our own specialty, have written off frontal lobe surgery as a therapeutic weapon for any illness short of chronic major psychosis. The type of patients necessarily selected from the big state hospitals for the early work in this field and the emotional flattening resulting from the wide, deep and extensive cuts originally employed, have set up a mental image of the lobotomized patient that it will take many years to erase, through current surgical progress and perhaps studies such

as this. It is significant of the general attitude that only one paper on frontal lobe surgery was scheduled at San Francisco for last year's APA meeting. Of this group of 13 who eventually came to either topectomy or pre-coronal leucotomy, 11 came to us with the expressed hope on the part of the referring physician that by the act of hospitalization and the further use of electroshock and tranquilizers we could somehow hold the line against progressive disintegration and self-destruction, surgery not even being considered. The remaining 2 patients were sent in specifically to determine the potential value of leucotomy for them as individuals. This proportion reflects the attitude of most psychiatrists.

In the non-psychotic group there are certain criteria that must be met by the patient. The first and most important of these is the history of an adequate pre-morbid personality. There must be evidence that the patient was able to live constructively with his neurosis and make an acceptable emotional adjustment before the intractable anxiety and agitation began to tear down his defences. We know definitely that topectomy and pre-coronal leucotomy will remove the anxiety but if there has never been a solid level to which to return it is doubtful if surgery is justified. Second, if extensive clinical and psychological investigation indicates an appreciable tendency toward paranoid formulations, or the possible release of aggressive and destructive behavior we have not risked surgery except in one patient. Admittedly, this restriction may have been too conservative, since in Great Britain there are now upwards of 20,000 post-operative leucotomies, and investigators of the stature of Sargant and Maclay have expressed the opinion that this danger is probably overestimated, particularly in the less extensive undercutting utilized here(9). A third important consideration to evaluate before surgery is the probable emotional atmosphere to which the patient will return after hospitalization. The attitude of the patient's spouse is particularly crucial since marital discord can occur when the returned patient, demonstrating much less dependency than during the months or years prior to surgery, threatens

the security of an authoritarian or immature spouse. In this small group we have had one divorce, another threatened divorce and a third situation, wherein the patient, freed of anxiety but showing no other personality change, had to "take over" as head of the family when her husband could no longer dominate her and himself retreated into a regressive neurotic pattern of behavior.

The importance of frequent educational contact with families is one of the reasons why we have practically demanded that patients remain in the hospital for at least 60 days after surgery. Of more direct importance to the patient is the fact that this period is felt to be very crucial to the eventual outcome. The convalescent weeks are divided roughly into thirds. During the first 3 weeks the patient will be quite slothful, will sleep a good deal to make up for lost sleep and exhaustion, will be hedonistic, humorous, probably sarcastic and quite tactless in conversation and relationships with others. The only limitations imposed are that he must stay on the hospital grounds, must have a nurse with him at all times and not engage in any activity such as heavy exercise or swimming that might endanger his post-operative physical status. He eats and sleeps when he pleases and is encouraged to behave in any manner he desires, within obvious limitations. After one month the night nurse is removed and pressure is gradually exerted to get him organized into a pattern of regularity in his sleeping, meal hours, hygienic routine, proper selection of clothes and the observation of good general manners and courtesy towards others. Usually this routine is established after about 6 weeks but we have found that if a patient is at home and continues to do as he pleases it may never be established. During the last 2 weeks the patient is usually put on his own responsibility, the day nurse is removed, he begins to go home for week-ends and plans for his future are discussed with him for the first time. Not until the last few days do we discuss his past illness, the reasons for surgery, or attempt to determine changes in his mental content following surgery. In general the patient is more than pleased to concentrate on the present

and future and expresses himself as "well rid of the past." Dilantin is continued for one year after surgery combined with ascorbic acid to prevent gingivitis.

Certain results have appeared so consistently in these patients that we feel they should be noted even though the small number of cases makes any statistical approach valueless.

1. With the surgical removal of pathological states of anxiety and tension there seems to be immediate cessation of the need for barbiturates and alcohol. It was the usual sequence of events that patients who had been unable to sleep at all without heavy sedation, and slept poorly even when heavily sedated, would sleep soundly on the night following operation and thereafter without hypnotics. The same general observation was also true of the daylight hours, wherein prior to surgery these patients kept up a constant pressure to obtain any drug, including alcohol, that would promote peace of mind through suppression of frontal lobe activity. We have not operated in any case to specifically influence this type of addiction but it might have much to offer.

2. We found, as have many others including Freeman, Sargent and Scoville (10), some remarkable somatic changes in those conditions known to be influenced by emotional tension. One patient, age 54, had been hospitalized 4 times for severe, bleeding ulcerative colitis, was maintained on a very restrictive bland diet and was told at her last hospitalization, 2 months before psychiatric admission, that her only chance of recovery was through colectomy. During the first week after topectomy, uninhibited by dietary restrictions she literally gorged herself on fresh corn, cauliflower, high residue salads, celery *etc.* stating in high good humor "even if it kills me it's worth it." She had no unfavorable reaction, has now been eating whatever she wants for 4 years and has had no further diarrhea, bleeding or other symptoms of colitis to present writing. One of us (J. L. P.) has a very similar case in his own series in whom ulcerative colitis was repeatedly demonstrated by sigmoidoscopy prior to leucotomy. She is now about 8 years post-op, has been clinically recovered since surgery

and routine proctoscopic and sigmoidoscopic examination demonstrated the rapid return to normalcy of the intestinal mucosa. Three of these patients, plagued for years with hay fever and asthma in June and September, noted a marked improvement in their allergies. Another patient, a 30-year-old paranoid schizophrenic, had truly emaciated himself and developed active, far advanced tuberculosis through refusal to eat. He had been given a total of 110 electroshock treatments in trying to combat this and on admission he still consistently refused food. Topectomy in this case was definitely a gamble but he has not missed a meal in 5½ years, his tuberculosis is entirely arrested and, although still a schizophrenic he is able to spend increasing numbers of weeks at home because he is greatly improved in health, mood and behavior. Only 3 of our patients were hypertensive but they showed a gratifying initial drop in pressure for several months, thereafter have gradually risen but are still not up to pre-operative levels. Nearly all of the patients seemed to drop years of age in their facial expression and appearance, with the ironing out of lines of fatigue and tension as well as a change of facial expression away from a chronically worried and haggard appearance. This was frequently brought to our attention by the visiting families, or the patients themselves.

3. Apparently no group of patients are as grateful to their physicians as those who have had relief of symptoms through frontal lobe surgery. Ordinary process of follow up seems largely unnecessary with this group because about 90% either write to us regularly, telephone or report back to the hospital from as far away as Texas and Arkansas. Questionnaires always get a total response and several patients have spontaneously volunteered to talk to prospective surgical candidates if they were fearful or hesitant about having surgery done. This was never necessary because once a patient surmounted the initial shock of contemplating brain surgery and could be actually promised relief he usually tried to advance the date of operation stating, "I would rather be dead than the way I am now." We consider this continued friendliness and desire to maintain contact long after leaving

the hospital to be a most gratifying result of the procedure. The well-known habit of the former patient snubbing his psychiatrist in public does not seem to prevail here. Perhaps this pleasant reversal of form has increased our enthusiasm for this therapeutic procedure.

A few brief observations are in order concerning the technical aspects of surgical treatment. They are contributed by our surgical co-author and are based on the follow-up of approximately 500 of his own post-operative cases, inclusive of this small group. Perusal of long-term follow up reports suggests that the surgical placement of frontal lobe lesions is important, whether it be by cortical ablation as in topectomy(3), or by disconnection of the thalamo-hypothalamic frontal white fibers as in lobotomy(4). Both topectomy and lobotomy studies indicate that best results with minimal intellectual or emotional deficit follow bimedial subfrontal operations (5) rather than operations on the lateral or superior aspects of the frontal lobe(8). It has also been established that the quantity of surgical removal or disconnection is significant(6). Too little proves therapeutically ineffective, while too much impairs the functional capacity of the brain. Another factor that must be weighed in gauging the surgical extent of these procedures is the degree of any existing brain pathology that may be encountered at operation, such as atrophy, discoloration, undue firmness of the convolutions, a milky arachnoid membrane or advanced arteriosclerosis(3)(6). Such findings, also noted by others(7) in about half the brains so visualized, may lead one to more conservative surgery than otherwise, since some degree of brain damage already exists. While the microscope fails to indicate the nature of these changes(8), they are grossly sufficiently prominent and prevalent to make one wonder about the possibility of metabolic, biochemical or other organic disease of the brain as the cause of the emotional disturbance in at least some of these cases.

Topectomy, a topical resection of a block of frontal lobe cortex(8), of proven value in its day, has now been discarded because it involves a longer and far more arduous

operative procedure than lobotomy, without achieving superior therapeutic results. In lobotomy, operative fatalities have been reduced from 3% to zero and no longer do urinary or fecal incontinence, post-operative hemorrhage, lasting euphoria or flatness of affect occur unless these conditions existed prior to surgery.

SUMMARY

A series of 18 consecutive patients were selected for frontal lobe surgery over a 10 year period to obtain relief from chronic, intractable anxiety. Of the 13 who were not psychotic, 12 have returned to a well adjusted, independent existence at home without further hospitalization or continuation of therapy. Certain observations based on these case studies have been made, with full realization that generalizations cannot be drawn from 18 cases and that whatever value this study may have is dependent upon intense personal investigation of all relevant factors in a small group of individuals.

CONCLUSIONS

1. Topectomy, or more recently modified leucotomy, is the treatment of choice for severe anxiety states that have proven resistant and intractable. Surgery offers, in our opinion, a far better chance of relief from the intense and disabling symptoms of guilt, self-recrimination, anxiety and the disorganizing effect of repetitive, uncontrollable patterns of obsessive thought than does any other form of therapy presently available.

2. It is not presumed that the operative procedure is in any way curative of the underlying personality disturbance that is creating intensely distressing symptoms but it relieves the suffering of the patient in a manner that appears prompt, predictable and permanent.

3. The procedure is safe. In the hands of a skilled and experienced neuro-surgeon there have been no fatalities and a carefully planned bimedial prefrontal lobotomy appears to carry little risk of rendering a patient worse in any way. In only one of this group of 18 cases has there been any undesirable side-effect. This patient had been actively psychotic and continuously

hospitalized for 18 years, requiring extensive, bilateral removal of tissue by topectomy in order to accomplish the relief of severe somatic delusions. During the 6 years followup she has had 3 grand mal seizures in spite of anticonvulsants but it has been a small price to pay for the relief of symptoms obtained. This complication represents 5.5% of the total series.

4. Based on long term clinical observation and psychological testing after surgery there has been no evidence of intellectual impairment, defects in concentration, retention or memory. In fact, the contrary has been repeatedly noted by patients and families as well as business associates. They report an alertness, organization and ability to concentrate that usually has not been present in that specific patient for months, sometimes years, prior to operation. The patients themselves explain this by the fact that their minds, free of self-recrimination, anxiety and fear, can return to normal function. One male patient, now almost 2 years post-operative, returned to full duty as chief auditor of a large industrial establishment 2 months after operation and is currently writing a highly technical textbook on cost accounting. One of us, (J. L. P.) has a private series of cases exclusive of this group, which consists of 27 men and women who today, 10 years after topectomy or lobotomy operation, are conducting a full and normal life and are responsible for committee work, business mergers *etc.*, so successfully that no one is aware of the fact that brain surgery has been done.

5. Careful selection of cases and prompt surgery before there is any deterioration of personality, or before excessive ECT creates an "electrical leucotomy," have been found to yield the best results.

6. The procedure has at least humanitarian value in providing relief from unbearable tensions in severely psychotic patients suffering from persistent somatic delusions.

7. The possibilities inherent in this safe procedure for the treatment of such conditions as severe ulcerative colitis, anorexia nervosa and even constantly recurrent peptic ulcers have not yet been even superficially explored in this country. Given any

choice, the authors feel that they would much rather undergo both the surgery and the aftermath of pre-coronal leucotomy than colectomy or gastrectomy, to say nothing of retaining an intact gastrointestinal system.

8. In view of the duration of symptomatic relief in these patients it seems reasonable to hope that the results achieved may be permanent.

M. E.	65-F	5	3	3 series 20	1 mo	Agitated depression	Discharged—still active & doing well	1	Unusually independent post-op.
N. R.	55-F	6	4	2 series 24	60 mo Outpatient	Agitated depression Intense anxiety	Home to resume full social & domestic duty	1	Abrupt change in personality—no residual anxiety

CRITERIA FOR THE SELECTION OF A SMALL GROUP OF CHRONIC SCHIZOPHRENIC SUBJECTS FOR BIOLOGICAL STUDIES.

Special Reference to Psychological (Family Unit) Studies

SEYMOUR PERLIN, M.D. AND A. RUSSELL LEE, M.D.

A review of the literature reveals little attention to the problem of the selection of schizophrenic subjects for biological studies(1, 2). In the published history of such research, the explicit theory or method underlying patient selection is rarely noted. Further, an analysis of the implied process indicates avoidance of such issues as the feasibility of random sampling, non-purposive sample bias, the range of variation with respect to such irrelevant and complicating conditions as age and hospitalization, and the means by which subjects may be duplicated in a pertinent manner.

A major area of interest of the Laboratory of Clinical Science at the National Institute of Mental Health lies in the application of the biological sciences to the problem of mental disease. A long-range multidisciplinary program of studies in the biological aspects of schizophrenia is currently in progress(3). For this purpose, a limited number of beds are available.

Since any program involving intensive psychological and biological studies will be limited with respect to the number of patients, the theory and process of the selection of the sample assumes considerable importance. So far as we know, no attempt has been made to bias a sample for biological studies in the manner to be presented.

It was felt at the outset that any sample chosen should reduce to a minimum those variables which are not characteristic of, or clearly relevant to, schizophrenia (in order to reduce the likelihood of false positives) and maximize the likelihood of inclusion within the sample of those forms of schizophrenia (if they exist) in which

biological abnormality plays a significant role. Further, appropriate criteria of selection once established could provide a basis for duplication and extension of particular findings in a larger group.³

RESTRICTION OF VARIABLES

This method of screening chronic schizophrenic subjects for biological studies presumes that chronic schizophrenia is a continuing psychophysiological process. (No assumption is made as to the possible modification of causal factors during the course of the disease.)

However, even if schizophrenia reflects a psychophysiological state, the latter may not be manifest except under certain conditions of stress. For example, the schizophrenic may compensate psychophysiological in such a way as to be indistinguishable from normal-controls; on the other hand, the schizophrenic may also decompensate under a stress such as criticism and may only then reveal an aberrant psychophysiological condition.

It is possible that the manifestation of chronic schizophrenia may be caused primarily by such social forces as hospitalization, in contrast to the manifestation of acute schizophrenia which may reflect an underlying physiological disorder. These considerations suggest the alternative and

³ Acknowledgements: We are indebted to the following colleagues at the National Institute of Mental Health for their advice and interest in the preparation of this paper: Dr. Seymour S. Kety, Chief, Laboratory of Clinical Science; Mr. Samuel W. Greenhouse, Chief, Applied Statistics and Mathematics Section, Biometrics Branch; and, especially Dr. Gordon Allen. Laboratory of Socio-Environmental Studies, Mr. Sidney Haddad, Mr. Paul Blank, Mr. Walter Ladusky and Dr. Robert N. Butler were instrumental in selecting subjects from the following hospitals: Springfield State Hospital, Sykesville, Md.; Spring Grove State Hospital, Catonsville, Md. and St. Elizabeth's Hospital, Washington, D. C. The cooperation of the staffs of these hospitals is gratefully acknowledged.

perhaps preferable screening of acutely disturbed students or military personnel and also childhood schizophrenics in future biological studies.

Restriction of the following variables is especially important since, under the conditions noted, they may be irrelevant to schizophrenia.

1. *Age*—A number of biological function patterns have been best described for normal subjects between 20 and 35 years of age. This suggests a comparable age range for patient selection. Below 20, biological patterns are apt to show the marked variation characteristic of the adolescent period. The upper limit of age 35 excludes a population in which aging is an important variable.

2. *Sex*—Male patients are preferable for the following reasons: (a) Many more "normal" biological values are already established for males. (b) The psychophysiologic phenomena of menstruation are avoided. (c) Dependable urine collection is more feasible in males.

3. *Race*—The possibility of pertinent and significant racial differences cannot be rejected *a priori*. Since most control studies have been done in white populations, and since the white schizophrenic group is larger and better characterized, purposive selection is easier in this group.

4. *Length of hospitalization*—The period suggested is between 3 and 5 years. On an initial screening, length of hospitalization is thought to be a more meaningful criterion than duration of illness because of the difficulty in evaluating historical data available at the time of a screening procedure. The minimum figure of 3 years hospitalization is in accord with data indicating that once a patient has spent 3 years in a hospital, his chance of being discharged is significantly decreased (4). This means that the group is more likely to be available for long-term biological studies and to fulfill, to a greater degree, those requirements for the diagnosis of schizophrenia based on prognosis. The maximum of 5 years is chosen in an attempt to limit the more extreme effects of long hospitalization. Within such a group, evaluations of psychophysiological compensation or decompensation

may be utilized as criteria for further selection (5, 6).

As noted, the acceptance of these limits implies the need for other samples or comparison groups comprised of acute schizophrenic patients who have not been hospitalized or who have been hospitalized for less than 3 years.

5. *Freedom from overt complicating factors*—Medical evaluation done as part of the screening process must maintain focus on factors related to both patient status and hospitalization which will alter related biological studies. For example, "training status" (7), which reflects the activity or inactivity of the individual should be considered in addition to nutritional status. Individual differences as well as the effects of hospitalization must be evaluated. Data regarding the administration of vitamins and antibiotics should also be noted. Many patients hospitalized for this period of time will have had insulin, electroconvulsive and psychopharmacological therapy. The amount of treatment given and any complications of therapy should be considered in selecting cases.

A DESIGN FOR SELECTION : A BIASED SAMPLE

Concepts of randomness and bias as applied to the selection of schizophrenic subjects.

Random sampling is frequently emphasized in the literature. In many projects, however, the randomness is clearly not within the total population of schizophrenic patients, but rather within a heavily biased subgroup which will vary from study to study. On one level this may represent the bias of a "random cooperative" sample, where cooperation is needed for collection of specimens, etc. Cooperativeness, in turn, may be highly correlated with a chronic versus acute subsample or with a paranoid versus a hebephrenic subsample. Many samples seem especially weighted by cooperative, chronic, paranoid patients.

Frequent biases for the selection of schizophrenic subjects are : patient cooperation, activity level, psychodynamics, subtype, symptoms, level of compensation, ability to have behavior recorded and

potential for a control.⁴ Such stratification results in subgroups within which random sampling can then be done. Our goal is not to sample a chronic schizophrenic population randomly but rather to bias our selection with reference to the biological studies. *An operational framework for considering organic versus environmental factors in schizophrenia and its relevance to the biased sample.*

For purposes of discussion, we may consider schizophrenia as a continuum of disease, at one end of which the etiology is organic and at the other, environmental. Organic and/or environmental factors may be involved in the expression of the disease as well. If schizophrenia consists of multiple entities, however, these same assumptions, for purposes of discussion, would hold for each entity or syndrome. Our purpose here is not to defend one point of view against another, but rather to indicate the consequence of such points of view in our operational approach.

We may examine this approach in terms of each of the following alternative postulates:

1. The primary etiology of schizophrenia is environmental: there are no *relevant* organic factors.

2. There are organic factors, but these are secondary to the environmental. (a.) Such organic factors are necessarily present. (b.) Such organic factors are variably present.

3. The primary etiology of schizophrenia is a single organic factor: there are no *relevant* environmental variables.

4. Organic and environmental factors are simultaneously etiological and relevant.

5. There are multiple entities within the "group of schizophrenias." For each entity 1, 2, 3, or 4 may hold.

These postulates should not be considered as composing in their totality a theoretical model of the etiology of schizophrenia; only those postulates are noted which would basically alter our screening procedure. (Concepts regarding the persistence

or sufficiency of these factors in the expression of schizophrenia may modify but will not be crucial in determining selection strategy.)

If the primary etiology of schizophrenia is environmental and there are no relevant organic factors, (postulate 1), no method of selection will increase the probability of finding significant biological variables. If the primary etiology is a single organic factor and there are no relevant environmental variables, (postulate 3), then the significant defect will be revealed by the appropriate biological test in *any* selection of schizophrenics. Under such circumstances, the randomness and the size of the sample are unimportant. Thus the biasing process, however incorrect in theory or application cannot exclude the desired subjects, i.e., those who would reveal the significant defect.

The necessary or variable aspect of biological findings, secondary to environmental causes (postulate 2) is not distinguished in our working design. Similarly, organic and environmental factors which are simultaneously etiological and relevant (postulate 4) are not distinguished in this approach. Hopefully the number of variable aspects may be reduced by restricting irrelevant variables in selection as well as in the management and evaluation of the experimental population; contributory information may be obtained through the use of ward observations, ratings of affective states, serial testing, etc., and in the concurrent evaluation of both the experimental schizophrenic sample and a contemplated normal-control sample(5).

Our working hypothesis assumes that there are multiple entities within schizophrenia or within the group of schizophrenias, (postulate 5); this is the least restricting assumption for our selection strategy. Only if important organic defects are inconstant, will the selection process affect the probability of their discovery; it is therefore on the basis of this postulate that the present theory of selection has been developed. Following from this, we seek to bias our selection in favor of the biological types of schizophrenia.

Process schizophrenia as the basis of a

⁴ See Perlin, S.: *Geriatrics*, 13: 747, Nov. 1958, for illustrations of non-purposive and purposive bias in the process of selection.

biased sample. One possibility of biasing a patient sample in favor of the biological types of schizophrenics lies in the selection of process schizophrenics. Hustin and Shatsky (9) define process schizophrenia as a psychiatric state "connected with an organic process" and then make reference to Bleuler's statement that process schizophrenia is in that class in which "there is a morbid process in the brain that conditions the psychosis."

The definition of process schizophrenia may also be derived from Kraepelin's original designation of a dementia praecox (10). Nevertheless although this concept is as old as the concept of dementia praecox or schizophrenia, the problem of clarification remains. (We are *not* now considering the so-called schizophrenic reaction which is related to a known organic abnormality, for example a schizophrenic reaction resulting from an epileptic focus.)

Although "process" is often equated with the "organic," there seem to be myriad ways of arriving at this equation which may be relevant to the proposition of bias.

One way would be the "organic by analogy" school. The following summary is from an article entitled "Schizophrenia and Central Nervous System Pathology" by Brackbill and Fine (11).

This study attempted to investigate some of the dimensions of schizophrenia. Three groups of subjects were studied: a group diagnosed as typical process schizophrenia, an atypical or reactive group of schizophrenics, and one with known central nervous system pathology. Rorschach protocols were examined for the incidence of Piotrowski's ten signs of organic involvement. It was found that the organic and process groups could not be distinguished from each other, but both of these groups showed significantly more subjects with at least five signs than did the reactive group. It was suggested that the difficulty in differential diagnosis of some kinds of schizophrenics and organics results from the involvement of central nervous system pathology in process schizophrenia. It is suggested that research findings would be less equivocal in studies of schizophrenics if this possibility were considered in the selection of subjects for investigations of schizophrenia.

Setting aside the question of reliability

of Rorschach diagnoses of organic involvement and of reasoning by analogy (that is, through the intervening variable of the psychological projective-technique test), we must still consider process schizophrenia in determining our selection bias.

Most frequently, process schizophrenia is viewed as a constellation of signs, symptoms and predictions. In such a constellation, the following items are usually considered: 1. The premorbid history and personality. 2. Signs and symptoms. 3. The "Non-Reactive" versus the "Reactive." 4. Implications of psychological tests. 5. Course and prognosis.

In general, the premorbid history is described as schizoid. This is derived from a pattern of behavior in childhood, adolescence and adulthood (12). The question of childhood schizophrenia may be raised. Exacerbation of maladjustment may occur in adolescence. A bizarre difference is usually in evidence. Premorbid performances in schoolwork, family relationships, social and sexual adaptation are said to prognosticate the malignant course and outcome (13). The increasing massiveness of symptoms is often noted. Symptoms usually emphasized include: depersonalization, derealization, pervasive ideas of influence, stereotypy, automatism, negativism, realization of disintegration of personality, etc. The onset is slow, insidious and from all available evidence not related to an acute or extreme stress (non-reactive versus reactive). Rorschach signs of organic involvement are present as are findings indicative of thought disorders. The course is regarded as progressive and deteriorating. Thus, regardless of the qualitative or quantitative aspects of symptoms, early improvement would render the diagnosis of process less tenable. In the general differentiation of process, asthenic and pyknic body types are said to be associated with the poor prognosis. Although there has been no systematic attempt to include a variety of biological test responses in differentiating process, many may be relevant.

It is important to emphasize that each of these items singly or in combination has been variously used as necessary or sufficient for the diagnosis of process schizo-

phrenia. Usually all of these concepts are blended under the definition of process schizophrenia. In our opinion, neither the equation, "process equals organic," nor the very definition of process has been sufficiently clarified for use in patient selection. Nevertheless one or more of the items noted may be used to examine subgroups and/or individuals within our sample. Thus, there should be the opportunity to compare process designations with genetic designations as well as with biochemical measurements.

Catatonic and hebephrenic subtypes as the basis of a biased sample. In such an approach, the assumption is made that one classical subtype is more likely to be biological than another. The evidence may include genetic and biochemical data. For example, Kallmann(14) found that the expectancy of schizophrenia is about twice as high for the children of patients in hebephrenic and catatonic groups (20.7% and 21.6%, respectively) as for those in the simple and paranoid groups (10.4% and 11.6%, respectively). Also according to Kallmann's data, there is a higher incidence of parental schizophrenia among hebephrenic and catatonic patients than among simple or paranoid patients.

Periodic catatonia is thought to epitomize this concept and many investigators consider this type a separate entity. Biological findings which relate to or precede recurrent episodes of illness have been reported(15).

A genetic approach as the basis of a biased sample. Planansky(16) summarizes the results of genetic studies of schizophrenia as follows:

The reported excess (as compared to incidence of schizophrenia in the general population) of the studied psychoses in close relatives of psychotic probands is an indication of a certain degree of genetic predisposition even if the expectancy rates are the result of several modes of heredity and even if some proportion of the cases is independent of any specific genetic determination.

Our strategy then moves one step further. We have noted our assumptions relating to the (inconstant) biological types of schizophrenia. At this point, we seek to define these types in terms of a genetic inheritance.

As indicated in the discussion of biological versus environmental factors, if genetic factors are unimportant, then our selection method may be irrelevant.

What approaches then have provided evidence for a genetic etiology of schizophrenia? And can any of these be utilized to bias our sample?

Twins concordant or discordant as to schizophrenia may be of use. In a number of reports, Luxenburger, 1938(17), Rosanoff, 1934(18), Kallmann 1953(15), Slater, 1953(19), a comparative investigation of concordance in hospital patients reveals that there is a significantly greater concordance in monozygotic pairs. The absolute values of concordance rates advanced by different investigators are of less importance than the marked difference in concordance between the two twin categories.

Are twins useful in obtaining a genetically biased sample? Allen(20) points out that "the relationship between identical twins is unique and despite the coefficient of relationship of 1, disease found in both members of a one-egg pair cannot so safely be attributed to a major hereditary defect as disease found in two ordinary siblings". Monozygotic twins, in addition to having identical genes, also have identical constellations of genes. Since this is so, any phenotypic, biochemical alteration found in such twins might be due not to discrete genetically determined characteristics but, instead, to a characteristic determined by the entire constellation of genes. Such a constellation might not be duplicated by other sets of twins nor by other non-twin schizophrenics. (Tests performed on concordantly schizophrenic identical twins may be nearly equivalent to doing the same test twice on the same individual and, therefore, to halving one's sample. Of course, one member of each monozygotic pair may be used instead.)

Similarity of environment for monozygotic twins has been used to question the emphasis placed on twin studies. One an-

⁵ If instead of a major hereditary defect, a complex genetic etiology were a central hypothesis for our selection, then monozygotic twins concordant as to schizophrenia, could constitute the desired biased sample.

swer to such questioning is the magnitude of the difference of concordance rates between mono- and dizygotic twins. The comparison of identical twins discordant for schizophrenia or else concordant but separated at birth, would permit useful and differential perspectives.

The existence of a schizophrenic gene or constellation of genes has been suggested but not established by analyses of sibships and other family groupings. Geneticists, analysing pooled data on schizophrenia, have been primarily interested in the underlying mode of inheritance, that is, whether of dominant, recessive or an intermediate form. In addition, the concepts of multiple additive factors and low penetrance have been utilized. Further, body build as a modifying influence controlling not only the penetrance of the gene but also phenotypic variation and the degree of malignancy, has been postulated. Several types of inheritance may play a role in the determination of schizophrenic psychoses.

Although twin studies are more widely known, family studies in schizophrenia preceded such studies and are more numerous. Indeed genetic theories originated in the observation of an increased incidence of schizophrenia in close relatives of schizophrenics. Biasing the selection in favor of patients with increased familial incidence seems reasonable.

If schizophrenia is etiologically diverse and includes cases with a simple genetic cause, these are the ones most likely to have underlying gross chemical pathology. In this manner we have thought of biologic in terms of inheritance, and have sought to link inheritance to the biochemical.

In planning the selection of schizophrenic patients for intensive biochemical investigations, it was decided that the widest sampling of genetic cases of the type desired would be achieved if one-fourth of the sample showed a family history suggesting dominance; one-fourth, a history suggesting recessiveness, and one-half, a negative family history. The rationale was that any common genetic type would be likely to occur among the patients with affected close relatives, but that any possible two-factor or semi-lethal dominant

type might be crowded out of the family history groups if a significant percentage of cases of schizophrenia is truly due to a common dominant defect, to polygenes, or to environmental causes. The patients with negative family history would then be more likely to include the uncommon genetic types; even common genetic types of schizophrenia are apt to enter the negative family history group if genetic types have a high incidence. Such patients could, by design, also include any distinct clinical types not found in the first half of the sample (21).

In a small sample, it is possible for our selective criteria to exclude the very group for which selection-bias is intended. Selecting one-half of the sample without (immediate) family history of schizophrenia renders this exclusion less likely. An additional argument for such a procedure is in the consideration of patients in the family history group as particularly disposed by their environment to schizophrenia; if this is so, the patients in the negative family history group may reflect the stronger genetic disposition.⁶

THE APPLICATION OF A GENETIC DESIGN IN CURRENT INVESTIGATIONS AT THE NATIONAL INSTITUTE OF MENTAL HEALTH

The genetic design is based on the presence of schizophrenia *within* the immedi-

⁶ On the other hand, we may also consider the patients in the Negative Family History Group as particularly disposed to schizophrenia by their environmental-learning situation and/or symbiotic, "pseudosupportive," ambivalent or "communicatively incongruent" relationship to a non-psychotic or non-overtly psychotic parent or significant "other." If this is so, the patients in the Family History Group may reflect the stronger genetic disposition. (Although we have indicated our operational assumptions we may conceptualize a series of genetic *and/or* psychogenic continua which may be useful in the study of family units containing a schizophrenic member.) As in the case of twins, individuals or siblings born into one family pattern, genetically or psychogenically defined, but reared from birth in a contrasting pattern or else a family without a schizophrenic member would permit useful and differential perspectives.

Within the group of patients or families selected by this primary mode of biased selection, random sampling may occur or else further purposive selection based on representation or distribution of sociocultural and psychological (personality) variables may be considered. In any case, such additional factors can be evaluated.

ate family of the patient. Even if simple Mendelian inheritance is unlikely, some family patterns of schizophrenia may be considered as more likely to be related to genetic factors than others. Affected relatives may constitute evidence for either recessive or dominant inheritance. Thus, there will not be a necessary correspondence between mode of inheritance and family patterns by means of which the cases are classified.

1. Family History Group: The Dominant Pattern. Typically a dominant pattern would require the presence of schizophrenia in one parent, 50% of the proband's children and 50% of the proband's siblings. Our *minimal* condition is one affected parent.

2. Family History Group: The Recessive Pattern. Typically, a recessive pattern would be fulfilled where neither parent is schizophrenic while 25% of the proband's siblings and a smaller percentage of his children are diagnosed schizophrenic. Our *minimal* condition is neither parent affected but with at least one affected sibling.

Examples will be given shortly of these two patterns.

Additional factors given positive weight in the selection of patients for either group include the presence of a normal sibling, the closeness, genealogically, of schizophrenic relatives and the frequency of schizophrenia in the entire family.⁷

Enviorns for two siblings, although diverse in many aspects will still share certain forces in common; the fact that such enviorns can also produce a normal sibling will be relevant. Appearance of disease in different (maternal, paternal) but related family units provides further evidence of etiology independent of the immediate family setting.

3. Negative Family History Group. Here the minimal requirement is availability of

parents and siblings to rule out presence of schizophrenia within the family unit.

As previously noted, there may be more evidence for genetic inheritance in one subtype of schizophrenia as compared to another. Recognition of the possibility of differences in genetic disposition between subtypes may be used to modify our selection procedure. (The different clinical pictures may reflect a variety of additional circumstances which are required for the expression of genetic factors.) Thus if certain types of schizophrenics are excluded by the familial criteria, restoration should be made of representative subtypes (e.g., simple, hebephrenic) in the Negative Family History Group.

Two examples of the Family History Group, Dominant Pattern, are seen in Figures 1 and 2.

Case 1: The patient (F. A.) is a 30-year-old single, white male hospitalized since April 1948. Diagnosis: chronic schizophrenic reaction, undifferentiated type with hebephrenic features. There has been no response to a variety of therapies.

The patient's family history is characterized by the fact that his mother, maternal grandmother, 2 maternal grand-aunts and 3 siblings have been hospitalized for schizophrenia. A maternal aunt has been hospitalized for mental illness, type unknown. Two maternal uncles are alcoholic. The oldest brother may be alcoholic. The mother was a patient at the time of his admission. She had been hospitalized on several occasions during his early life and has been continuously hospitalized since the patient was 13 years of age. He is the fourth of 6 siblings. A sister died in infancy of a "bowel disorder."

Case 2: The patient (Q. M.) is a 29-year-old, white, single male who has been hospitalized almost continuously since November 1950. Diagnosis: schizophrenic reaction, paranoid type with catatonic features. Hallucinations are prominent. There has been little apparent alteration of course with therapy.

Family history reveals that his mother, father, brother and sister have all been diagnosed as schizophrenic during the course of outpatient evaluation and therapy. A maternal uncle described as eccentric has also received psychiatric treatment. Only the patient and the maternal grandmother have been hospitalized for schizophrenia.

⁷ The operationally defined dominant and recessive family patterns, these additional factors and many others will be relevant to criteria for the selection for longitudinal studies based on the expectancy of the appearance of schizophrenia within such families. The sample should also include negative history families and families without a schizophrenic member, for comparison. Thus both psychogenic and genetic hypotheses may be studied.

Paranoid Schizophrenic, hospitalized, 1948

Figure 4. NEGATIVE FAMILY HISTORY (CA)¹

Hospitalized for Schizophrenia

d died

1 Index Case is a 33 year old Chronic
Paranoid Schizophrenic, hospitalized, 1953

An example of the Family History Group, Recessive Pattern, is seen in Figure 3.

Case 3 : The patient (I. L. L.) is a 36-year-old, divorced, white male with 3 children. He has been hospitalized almost continuously since 1948. Diagnosis : chronic schizophrenic reaction, paranoid type. His symptoms, including hallucinations, continue but he has adjusted to a withdrawn ward life.

Family background history revealed his parents were not psychiatrically ill and had never been hospitalized. However, a maternal uncle and a paternal uncle were hospitalized for schizophrenia. In addition, one of the patient's 10 siblings, a sister, was hospitalized for 11 years because of schizophrenia. None of the other siblings has ever been psychotic.

An example of the Negative Family History Group is seen in Figure 4.

Case 4 : C. A. is a 33-year-old, white, male, single, college graduate who has been hospitalized since July, 1953. Diagnosis : chronic schizophrenic reaction, paranoid type.

This patient's family history is, to the best of our knowledge, completely negative for schizophrenia. The family is characterized by high achievement. The patient's paternal grandfather and father are both educators. The patient's father is the oldest of 5 successful siblings. The maternal grandfather was a successful businessman. The patient is the second of 4 children. The oldest brother is an engineer and married. The patient's older sister is married to an engineer and has 2 children. The patient's younger sister, a teacher, is also married.

A scale for familial incidence may be

utilized in the selection and evaluation of schizophrenic patients. The scale found in Table 1 provides a numerical score based on the sum of the coefficients (or closeness) of relationship of affected individuals to the index case, each sibship being represented only once(20).⁸ Family data are also recorded in the notation of the pedigrees in Figures 1 to 4. Each key contains a number of symbols which may be used in each family-figure position ; symbol as well as position may be coded.

One implicit but major hypothesis in the rationale for coding evaluations of a number of factors, *e.g.*, familial incidence, genetic pattern as well as diagnoses, *etc.*, is the possibility that biological findings are often averaged out by comparisons between series of schizophrenics and normal controls. Even when there are one or more deviant findings, the usual approach is to repeat the experiment with another sample. However if subtypes exist, on whatever basis, it is possible that the next sample may not include a similar representative. If the finding is a borderline one, or perhaps emerges as a "cluster" within a normal range of values, the means for repeating and substantiating such data become even less likely.

Thus, by the use of criteria for selection as well as in the coding of identifying data, it should be possible to provide similar sub-

⁸ This particular scale emphasizes dominant inheritance ; another scale might be devised to emphasize recessive inheritance.

jects from previously screened reserves. This, of course, can be progressively differentiated. In addition, it would be possible to intensify a distinguishing characteristic, e.g., a similar individual from a family history of recessive pattern, but with further indications of recessive inheritance. Obviously the biochemical differentiation of new subgroups would be in itself an important contribution.

Utilizing the criteria for selection as described, the patient population of 3 nearby hospitals was screened. Modification of the criteria for selection was necessary. Table 2 compares the selected Family History and Negative Family History Groups with the initial criteria for their selection. Table 3 reveals the decreasing number of

subjects available as additional criteria for selection are imposed, i.e., male, white schizophrenic, age range, duration of hospitalization and familial pattern.

Data on schizophrenic patients from Family History and Negative Family History Groups, accepted for admission to the National Institute of Mental Health, are presented in Table 4.

The biological bias was kept primary and environmental factors were not considered in selection. Clinical status variables are also secondary in selection, but are likewise evaluated. Such additional data may in turn provide even more discriminating criteria for selecting new subgroups for biological studies.

TABLE 2

COMPARISON OF FAMILY HISTORY AND NEGATIVE FAMILY HISTORY GROUPS WITH INITIAL CRITERIA FOR SELECTION

	Initial Criteria	Family History Group	Negative Family History Group
Diagnosis	Schizophrenic	Schizophrenic	Schizophrenic
Sex	Male	Male	Male
Race	White	White	White
Age Range	20-35	29-41	25-37
Years Hospitalized	3-5	1-18	3-14
Availability of Parents	Alive and available	*	Alive and available

Hospital records available for all family members diagnosed schizophrenic

TABLE 3

SELECTION OF SCHIZOPHRENIC PATIENTS FOR BIOLOGICAL STUDIES: FAMILY HISTORY AND NEGATIVE FAMILY HISTORY GROUPS

	Referring Hospitals			Total
	I	II	III	
Number of Patients	2,800	3,500	7,200	13,500
Male	1,270	1,600	3,660	6,630
Schizophrenic	620	760	2,100	3,480
Age Range, 15-45 years	290	310	867	1,477
Age Range, 18-40 years, white, male Schizophrenic ;				
hospitalized more than 1 and less than 15 years	138	105	168	411
Family History*	24	15	20	59
Admitted	5	2	1	8
Negative Family History *	105	89	137	331
Admitted	2	2	2	6

* Only those members who clearly met the criteria for Family and Negative Family History designations are included. Histories for 21 families were insufficient for diagnostic purposes. Totals may be somewhat modified on the basis of on-going evaluations.

*** Consensus diagnoses as yet not formulated.

Many questions relating to the biological and/or psychological may be raised by the composition of our Family History and Negative Family History Groups. (*The selection of schizophrenic patients for participation in family studies alone may be based on similar criteria.*) In what ways is the mother of one schizophrenic offspring different from the mother of 2 or more schizophrenic offspring? How do schizophrenics without a model for psychosis compare to schizophrenics in a family with 1, 2 or more models? How similar are such models? If there is schizophrenia in 3 generations and also related schizoid and healthy individuals in the family group, what information can be gleaned as to common psychological or biological findings? The selection of normal-control volunteers (2, 8) extends these research areas.

We may conclude that the process of selection of schizophrenic subjects for research study becomes an important part of the research itself.

SUMMARY

1. The method of selection of a small group of schizophrenic subjects for long-term biological studies is an essential part of the research. In developing criteria the following concepts are considered: (a) range of variation of irrelevant variables, (b) random sampling, nonpurposive bias and purposive bias, (c) extension of the sample and intensification of pertinent characteristics of patients through the process of selection and evaluation.

2. Variables presumably irrelevant to schizophrenia are restricted: e.g., age, sex, race, length of hospitalization and complications of hospitalization and treatment. The acceptance of limitations inherent in a chronic schizophrenic sample presupposes that schizophrenia is a reflection of an ongoing psychophysiological process (which however may appear only under certain operant conditions). The need for the study of acute schizophrenic and other samples is stressed.

3. An operational framework for biological versus psychological factors in schizophrenia is considered; the assumptions involved are tabulated. The working hypothesis assumes that there is a group of schizophrenias. Within this framework, process schizophrenics, catatonic and hebephrenic subtypes and twins concordant or discordant as to schizophrenia are discussed as means for sample bias.

4. A genetic-familial design is presented as the basis for a biased sample. It was decided that the widest sampling of genetic causes would be achieved if one-fourth of the sample had a family history suggesting dominance; one-fourth a history suggesting recessiveness, and one-half a negative family history. The patients with negative family history would be more likely to include an uncommon genetic type and also would render less likely the exclusion of the very group for which selection-bias is intended. The minimal conditions are as follows: (a) Family History Group—The Dominant Pattern; one schizophrenic parent; (b) Family History Group—The Recessive Pattern; neither parent affected but with at least one affected sibling; (c) Negative Family History Group; no history of schizophrenia within the family unit.

5. The decreasing number of subjects available from a patient population of 13,500 in 3 collaborating hospitals is noted as the following additional criteria are imposed: diagnosis of schizophrenia, male, white, age range 18-40, duration of hospitalization of more than one year and less than 15 years, and familial pattern. A comparison of Family History and Negative Family History Groups with the initial criteria for selection is made; data referring to the first 14 admissions are presented.

THE PRACTICE OF PSYCHIATRY IN ENGLAND UNDER THE NATIONAL HEALTH SERVICE, 1948-1959¹

A. SPENCER PATERSON, M.D.²

It is a great privilege for me to be given this opportunity of reporting to you on the practice of psychiatry in England during 10 years of the National Health Service. I shall try to answer the questions, "How far has the psychiatric patient benefited, and what has been the impact of the Service on the psychiatrist's freedom of action and on his professional standing?"

In the last 25 years there has been an unparalleled advance in our knowledge of mental illness, especially in the sphere of therapeutics, and the world owes much to American medical science for originating or developing a number of fruitful procedures. Many British psychiatrists, like myself, owe a debt to American teachers which can never be adequately repaid. I was assistant in psychiatry at the Phipps' Clinic under Adolf Meyer and worked in Britain with the distinguished expounder of his doctrines, Sir David Henderson. I have also had the privilege of observing pioneer work at different centres in your vast country in the course of 3 previous visits.

When the visitor reflects on some of the greatest achievements of American medicine, he will no doubt realise that behind these achievements lies a tradition of individual freedom and enterprise, of healthy competition, and also of social service on the part of professional men and other citizens. At the same time the visitor may be led to doubt whether the medical profession together with the civic authorities and voluntary organisations have up till now created an efficient enough instrument to bring the benefits of all these medical and psychiatric advances to the average sick patient.

A study of recent American medical literature confirms the impression that there is an impending crisis with regard to medical administration. A statement for instance

made by the Board of Trustees of the American Medical Association runs as follows:

We can all agree that the American people should have access to the best possible health services. There is no debate on this specific objective. There is however divergence of opinion as to how and when this can best be accomplished (2).

This divergence of opinion apparently reflects the question whether private insurance will be the main instrument in providing the necessary services. Certainly at the present time medical insurance does not appear to provide an adequate answer to the problem of treating the psychiatric patient. A recent writer in the *American Journal of Psychiatry* states that only 10% of America's population is in a financial position to "buy" psychiatric care on the traditional "fee for services" basis.

Thus 90 percent of our fellow citizens must look to the Government or private philanthropy to help them, or they borrow and build up a crushing burden of debt; or they just go without treatment. . . . In this country, current pressures for additional and more available psychiatric services can push us toward Government responsibility for all forms of psychiatric care.

The writer then says that there is another possibility which is more in line with social evolution in America. This would be a working partnership of voluntary and individual effort with help from the Government (1).

The degree to which many Americans are afraid of this Government help may be judged from the statement of a past Vice-President of the A.M.A. when discussing a dispute between the A.M.A. and the Veterans' Administration. He writes:

The Veterans' Administration program is expanding government control over the nation's medical care system and is providing a big entering wedge for a complete Federal health program covering the entire population.

¹ Read at the 115th annual meeting of The American Psychiatric Association, Philadelphia, Pa., Apr. 27-May 1, 1959.

² West London Hosp., London, Eng.

The writer went on to state that the American Legion and the A.M.A. should be working together in the fight against Communism and also to defend the free enterprise system and to build up a positive understanding of Americanism (11).

We in England can sympathise with our American colleagues when they are apprehensive with regard to the ultimate consequences of submitting the medical profession to some degree of Government control. We had some of these same fears in 1948, but I am bound to say that after 10 years of the National Health Service, most psychiatrists would agree that the benefits which have accrued to the average citizen who is suffering from neurotic or psychotic illness, and also certain improvements in the conditions of work for the psychiatrist have up to the present at least outweighed any disadvantages of the system.

The distinguished writer whom I have just quoted mentions Communism but there are of course many essential differences between the National Health Service in England and the system of state medicine in Russia. I cannot speak with authority on the Russian system, as I have not visited that country since 1929, but some of its characteristics have been described in the following terms. Medicine has been entirely subjected to the goals of the regime. The Government could not therefore tolerate any independent professional body of doctors. The medical man does not apparently think of himself so much as practising a profession as being a member of a Trade Union. According to Russian ideology the aim of the medical profession is to prevent and to treat illness because it hinders productivity. The Russian physician is thought by foreign critics to be imbedded in a bureaucratic structure which is controlled by a political party. His first duty is thought to be not to the patient but to the State.

Under such a system various evils are said to ensue. Unsuitable orders reach the periphery from the central authority and these must be either disobeyed or else "formally" obeyed but disobeyed in spirit. This is obviously bad for the morale of the physician, while the administrators working at a distance get out of touch with what

is happening at the doctor-patient level. It is said that initiative and enterprise at the periphery are stifled by too many directives from the central authority. Further, conscientious practitioners may be intimidated by threatening letters in the Press or by branches of Trade Unions. The authorities may favour the appointment of a doctor to a responsible post by reason of his politics rather than for his technical skill.

These are some of the criticisms directed against the Russian system by refugees who eventually reached America from the Soviet Union. Nevertheless these same refugees stated that this system of medical care had hitherto been unsurpassed in their country and even those refugees who had personally had unfortunate experiences under the system emphasised that in their opinion some form of state medicine was preferable to one based on free enterprise (5).

Medical men in Russia after the Revolution were faced with a different problem from that which existed in England in 1948. Their task was to create a health service as quickly as possible for their gigantic population where almost no service already existed, and so they went about the problem, not unreasonably, as if they were planning a huge military campaign. The enemy in this case however was not a hostile state but disease in its various forms. But when the National Health Service was introduced into England in 1948, the situation was quite different. The new British service did not entail a complete break with the past. On the contrary the aim was to absorb all that was good in the existing services into the new scheme. Parliament intended that the benefits which had been available only to insured persons, or to those who could afford them, or receive them as a form of charity, should now be available to everyone. At the same time the essential freedoms were to be safeguarded. The citizen was free to use the Service or any independent part of it, as he pleased. He was free to choose his own doctor and to change to another if he so desired. The doctor on his part was free from interference in his clinical judgment and was free to make any criticisms of the Service which he wished. He could accept

private patients while taking part in the Service, or again, he could have an entirely private practice and so remain outside the Service.

It should be noted that the creation of the National Health Service did not constitute a Party issue but was supported by all Parties, including the Conservatives. The Service is now being used by 97% of the population. The great majority of specialists, 90% of family doctors, and almost all druggists, are co-operating in the scheme.

It is of interest that when the scheme was initiated the late Lord Horder founded the Fellowship for Freedom in Medicine. This body has regularly published a journal which keeps a close watch on the medical man's professional freedom and interests. It has recently advocated a system of State Insurance through which it is hoped to save more of the Exchequer's money while giving more responsibility to the family doctor. There is however almost no chance that this scheme will be supported by any

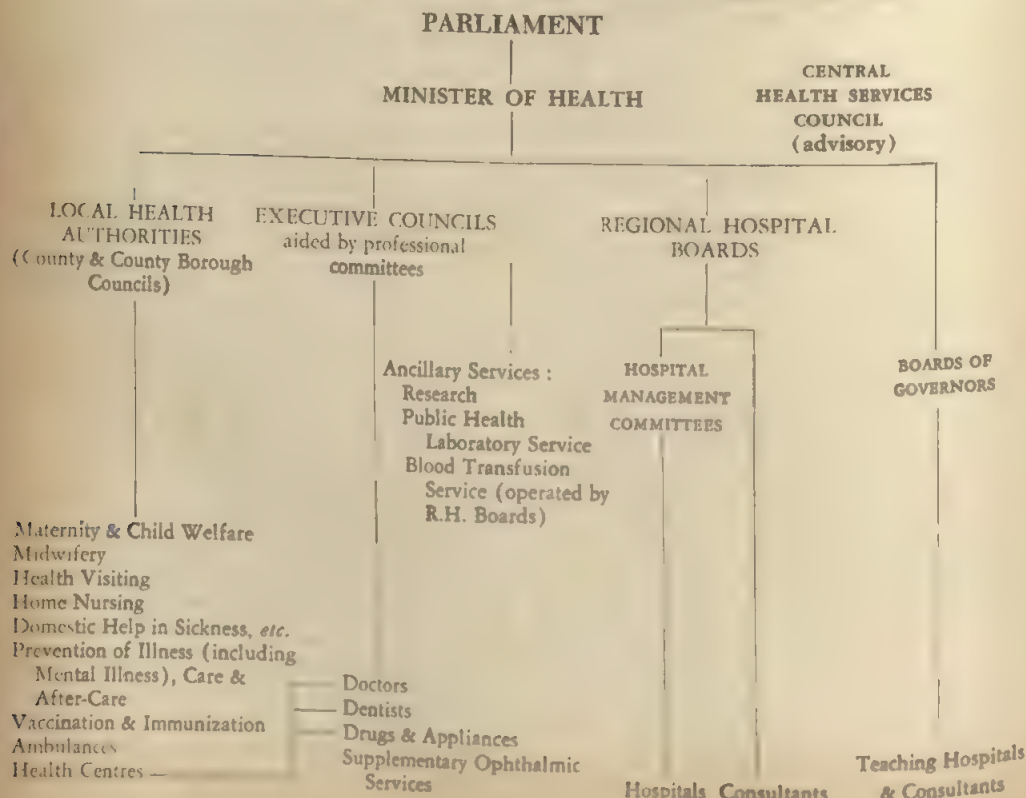

political party. The present system is too popular with the public for that. There is however an increasing number of citizens who are taking out private health insurance policies, but this is no reflection on the efficiency of the National Health Service because most patients who do this are merely aiming at securing better amenities during treatment. A proportion of them however pay sufficiently high premiums to enable them to have treatment wholly outside the Service. This development will therefore entail more private practice for the part-time psychiatrist in the future.

THE MACHINERY OF THE NATIONAL HEALTH SERVICE

The Service in Britain is administered centrally by the Ministry of Health advised by a Central Health Services Council and various committees. There are 3 main divisions of the Service(6).

1. Hospital and Specialist Services.
2. Local Authority Services. After-care,

TABLE 1
ORGANIZATION OF THE NATIONAL HEALTH SERVICE IN ENGLAND AND WALES

maternity and child welfare, midwifery, health visiting, domestic help in sickness, prevention (e.g. vaccination), ambulances and health centres.

3. Practitioner and Dental Services.

With regard to the first division, the 14 Regional Hospital Boards, which look after regions with populations varying from 1 to 3 million, are responsible for all the mental hospitals (147,000 patients) and all the mental deficiency hospitals (60,000 patients) and for the outpatient services (3, 8).

Secondly, the Local Health Authorities are responsible for the care of the defectives in the community (80,000) and for the prevention of mental illness and for the after care of those who have been in mental and mental deficiency hospitals. The Medical Officers of Health are now tackling the problems of mental health which impinge on their sphere of activity with the same enthusiasm with which they had previously overcome the threats of infectious diseases such as cholera, enteric fever, diphtheria, and the like. Their Society has recently established a mental health group and there is now more psychiatry in the syllabus of the course for the Diploma of Public Health. There is therefore good reason to hope that with these new-found allies, we psychiatrists will make still further progress in the coming years in our struggle against mental ill health.

Thirdly, the family doctors are much more interested in psychiatry than formerly. The newly founded College of General Practitioners has published a Report (4) which discusses such questions as how to improve the quality and quantity of psychiatric education both for the undergraduate and for the postgraduate practitioner. The family doctor in the future may be expected to look after the mental health of his patients with more understanding than previously when he relied mostly on intuition.

BENEFITS ACCRUING TO THE PSYCHIATRIC PATIENT FROM THE NATIONAL HEALTH SERVICE

The first indication in the campaign against mental ill-health was to treat as many patients as possible and at as early a

stage in their illness as possible. Accordingly some 500 new outpatient departments have been started in the past 2 or 3 decades and many of these in the past 10 years. They are mostly attached to general hospitals (9). Where the hospital is a teaching one, there is generally a number of beds which are used for research and teaching. It is reckoned that the psychiatric patient is willing to go to such a clinic 12 or 18 months earlier than he would be willing to go to a mental hospital. There has been at the West London Hospital an increase in the number of patient-sessions per annum since 1945 to the extent of about 500%. The number of psychiatrists has gone up from 3 to 10 and the non-medical staff has been correspondingly increased.

There has also been continuous research, mostly into active methods of therapy, particularly electrocerebral treatment, ataractic drugs, and hypnosis. These are subjects suitable for research in a general hospital where collaboration with colleagues in other disciplines is possible. This does not mean that psychotherapy is neglected. However, as in America, much thought is given to the possibility of shortening the duration of treatment while achieving an equally good result.

Our clinic is merely one of many, but when such clinics are multiplied to the extent of some hundreds, then results begin to show in statistics.

Not only has the number of clinics increased, but under the National Health Service the number of consultants has increased to a greater extent than in any other specialty. In 1949 there were 405 but in 1957, 614, an increase of 52% compared with an average 32% increase in other specialties. Similarly the trainee-specialists (senior registrars) have risen from 113 to 144, a greater increase again than in other branches of medicine. This should be of interest to American psychiatrists, for recent publications have deplored the lack of trained psychiatrists in mental hospitals (10).

The training of the psychiatrist is much more thorough nowadays than it was before 1948. He is encouraged to take a higher diploma in internal medicine as well as one in psychiatry. He is expected to be as equally at home in giving different

forms of physical treatment as he is with psychotherapy. Young psychiatrists, especially those residing near London, often undergo at their own expense a long and expensive training analysis with a view to future practice of this method.

With regard to inpatient treatment in mental hospitals, this can be conveniently divided into short stay and long stay. Since 1946 the number of patients admitted to mental hospitals has much more than doubled, from 36,000 to 84,000, an increase of 125%. The percentage of patients discharged within 3 months has risen from 50 to 55% in 2 years, and from 65 to 69% for those discharged within 6 months. This more than doubling of the numbers of short stay patients has of course greatly increased the amount of work done by mental hospital psychiatrists, but the actual number of beds occupied has actually fallen within that period by 1,353(9).

Recently however, there has been an even more striking trend. The question was asked, why should not a large proportion of these short stay patients be treated outside a mental hospital? Dr. Carse in 1956 organised "The Worthing Experiment" in which psychiatrists visited patients in their homes and, where necessary, gave them energetic treatment in an outpatient clinic or day hospital. It was found in this way that in a rural area a reduction in the rate of admissions by 57% could be achieved. A surprising feature of this study was that a high proportion of the patients who recovered without going into hospital belonged to the class over the age of 65, where one would have supposed that the prognosis was particularly poor.

With regard to the long stay patient equally striking experiments are being carried out(7). As in America, the greatest efforts are being made to rehabilitate long stay patients who have shown some response to treatment with electroshock and ataractic drugs(12). The services of experts in sociology and group psychology have been enlisted, as at Netherne under Freudenburg(8). Elaborate measures are taken to train the nursing staff and secure their co-operation in what is a particularly arduous task. The patients are gradually subjected to work therapy, and at Banstead

a factory actually exists inside the hospital. These measures are carried out in a particularly humanitarian atmosphere. There is a growing tendency to do away with locked doors. Attempts are made to invest the recovering patient with a new dignity. He is now called "Mr. Smith" instead of just "Joe." There is an increase in the mingling of male and female patients with a notable improvement in their manners and behaviour.

Before this new development the percentage of patients who had been in a mental hospital over 2 years and who became well enough to leave the hospital was only 2% per annum. It is likely however that in the future this figure will be increased to 10 or 20%.

It is because of the rise in numbers of successfully treated short stay patients and to a lesser degree of long stay patients that the Royal Commission on Mental Disorder and Mental Deficiency, 1956, was able to recommend new measures which are incorporated in a Bill now before Parliament (8). One result of this will be to arrange for the more effective care of recovered mental patients and improved mentally defective patients in the community. New measures will include the establishment of hostels, day hospitals, homes for the aged and the like. The new Mental Health Bill also aims at a more rational approach to the problem of mental disease, bringing it more into line with the rest of medicine.

I realise of course that the great advances in treatment to which I have alluded, have been equalled, or even surpassed, in some other parts of the world, especially America, but the point I wish to make is that in our country the improvements in therapy have been brought to the ordinary citizen to a far greater extent than would have been possible if it had not been for the National Health Service. It is certainly true that any fears which might have been entertained that socialised medicine might stifle initiative among practitioners working at the periphery have not been realised. On the contrary, there has been a new enthusiasm which has in large measure been responsible for these new developments.

It may perhaps be added that the smooth running of the Service has been helped by particularly good relations which have ex-

isted between psychiatrists and the public, the latter including members of the Civil Service. This goodwill has been greatly fostered by a series of programs on radio and television, and in the press. It is to be hoped that such publicity will continue, because only in this way will the citizen appreciate what he is receiving in return for the taxes which he pays to support the Service.

PRIVATE PRACTICE UNDER THE NATIONAL HEALTH SERVICE

Only 2% of approved mental patients are treated privately(9) but in spite of this there is still a considerable amount of private practice in psychiatry, mostly in urban areas.

In the years before the war the prospects of a career in psychiatry were not very attractive. An article in the *British Medical Journal* in 1937 stated that nearly all psychiatrists were whole-time officers in mental hospitals and that the pay was poor and the chances of promotion were limited. A brighter prospect however was presented to the relatively small number of psychiatrists who could procure a post in a general teaching hospital where they could combine the teaching of students with opportunities for research and also carry on a consultant practice. Such a life however would be a hard one with little time for leisure and their hospital work would not be remunerated.

In London and some other cities there were also doctors specialising in psychotherapy and there was the Institute of Psychoanalysis. One-third of the psychoanalysts had no medical degrees. Many so-called psychotherapists had no senior qualification.

The following were some of the changes which occurred in the mode of life of the consultant at a teaching hospital, when the National Health Service was initiated in 1948. We were no longer honorary psychiatrists at our hospitals but received salaries for our attendances there. We were free to decide whether we would work for any number of half days up to 9 in the week, 11 half days being counted as a full week. Most of those working 7 or 9 half days are employed at more than one clinic. We were of course free to remain outside

the Service if we so desired.

For those working full time the salary scale is roughly as follows: A young consultant at the age of 30 has about £2,000 a year rising to a maximum salary of £3,385 a year. There is however a system of merit awards by which 20% obtain an additional £500, another 10% an additional £1,500, and another 4% an additional £2,500 over the basic salary. Recently the sum of £300 has been subtracted from the highest merit award and £200 from the second highest, apparently indicating a new egalitarian trend.

The pension amounts to 1.5% per annum of all the money which has been earned under the Service. This compares favourably with other schemes of a like nature.

The Ministry encouraged psychiatrists to visit patients in their own homes. In this way the specialist can discuss the case with the family doctor and also observe the family setting. In many cases this has enabled active steps to be taken at the earliest possible stage of the illness. The psychiatrist is paid 4 guineas (about \$12) for the visit, plus a travel allowance. He may earn some 800 guineas a year over and above his basic salary in this way.

The same applies to the full time man but in his case the first 28 visits in each quarter are unpaid except for the travel allowance.

Those who prefer whole time service have benefited under the Service because a number of new and attractive posts have been instituted. There have been 9 new whole time professorships at provincial universities, and some two dozen appointments of whole time research workers who initiate and organise research projects which are often common to different hospitals in the same group.

For those who are part time there is still a great deal of private practice in London. As already mentioned there is an increasing number of citizens who have taken out a health insurance policy. This will enable the patient to see the psychiatrist privately and to obtain better amenities under the Service. If the premium is high enough it will enable the patient to receive treatment in an expensive room under the National Health Service or else outside the Service altogether.

There is another source of private practice. There are many visitors from overseas, especially in summer. These are not British subjects but are glad to avail themselves of recent progress in psychiatric treatment. They often provide a colourful change from our more humdrum work.

There still appears to be a considerable demand for private psychotherapy in London and possibly to a lesser extent in other cities. In addition to the part-time consultants already mentioned, there are a number of psychotherapists who do private practice but who also work at a clinic like the Institute of Psychoanalysis. There are also practitioners who are entirely in private practice. Many of these write books on popular psychiatry for the general public. Some of them, however, have not had any adequate training nor any diploma in psychiatry, and are sometimes referred to as "consultoids." Their success to some extent depends on the fact that the public as a whole looks on a Harley Street address as a kind of medical degree. By way of contrast to these practitioners there are a number of distinguished psychiatrists who have retired from the Health Service and who are now in full time practice. A few psychiatrists of repute work in private institutions and also engage in consultant practice as well.

CONCLUSION

In conclusion I should like to say that in America and Britain psychiatrists are striving towards the same goal, for we are trying to give the best possible psychiatric treatment to the greatest number of citizens who require it. In Britain however it

was decided after the war to conduct the struggle against mental illness at the National level. I have therefore attempted to give you some account of how far our efforts have succeeded and of how far in doing so we have preserved our ancient tradition of professional freedom.

PSYCHIATRIC DAY HOSPITALS¹

MICHAEL CRAFT, M.D., M.R.C.P. Ed., D.P.M.²

A day hospital may be defined as one where full hospital treatment is given under medical supervision to patients who return to their homes each night. It offers an alternative to inpatient admission to those for whom outpatient treatment is inadequate. It is suitable for those of the mentally ill who are well enough to travel and to spend the night with their families.

REVIEW OF LITERATURE

In North America, Cameron(6) in 1947 described day hospital care in Montreal and first introduced the term to Western literature. He treated "early . . . or mild advanced types of schizophrenia. Both hypomanic and depressed patients have been successfully treated." There were both hallucinated patients and those with suicidal ideas. An important function of this unit was the care of convalescent inpatients. He stressed cheapness, swiftness of recovery and importance of easy transfer to bed wards. These have been recurrent themes in later publications.

The Menninger Clinic day hospital started in 1949, and Barnard *et al.*(3) reported that one-third of all patients were treated on a day basis. It provided foster homes for patients who lived out of town. The 109 patients stayed an average of 70 days each and 90 were convalescent inpatients. The patients included 33 schizophrenics and 33 with character disorder.

Moll(17) founded a day hospital in the Montreal General Hospital in 1950 on Cameron's pattern. He used all forms of treatment except coma insulin. Depressive illnesses occur first on his list of diagnoses, although no figures are given. He found acute psychotics and defectives unsuitable. Many of his patients were not sufficiently ill otherwise to need inpatient care.

Pottle(18) runs a day hospital in sparsely populated Newfoundland. Government subsidized transport and lodgings ensure attendance of patients at a specially designed day care unit in the first floor of a new mental hospital. All forms of treatment including coma insulin are given, one irreversible coma occurring in 5 years practice. Landladies are instructed in the treatment of hypoglycaemia.

Cameron, reviewing 9 years practice (7), decided that, as transfers from day hospitals to inpatient wards were "infrequent," the former could well be independent. However, patients with suicidal ideas and disturbing behaviour could best be treated first as inpatients. One suicide occurred in the period reviewed. He feels that coma insulin treatment is quite satisfactory on a day care basis.

Bierer(4, 5) described the first day hospital in England. It is entirely independent of mental hospitals. The frequency of attendance by patients varies from 1 to 12 or more times a week. It is designed to function as a community centre. All forms of physical treatment, apart from coma insulin, are used. He advocates group treatments and the advantages of independence are stressed.

Aron and Smith(1) describe the Bristol day hospital. Geographically apart, but run by Bristol mental hospital staff, transfer of patients to and from the mental hospital is simple. Forty-four percent of the patients had depressive illnesses. The average number of days attended was 21, attendance becoming less frequent as the patient recovered. Smith(19) reviewed 1,000 Bristol day hospital patients, of whom 16% had been convalescent in patients and 10.4% had needed transfer to bed wards. The proportion of depressions treated had risen to 57% in 1955 and 9% had schizophrenia. Coma insulin had not been used.

Cosin(8, 9) describes a geriatric day hospital. Since it is run as part of a geriatric hospital the 70 day patients required no extra medical staff.

Harris(13, 14, 15) has reviewed the de-

¹ I am indebted to Professor Aubrey Lewis for his encouragement and to Dr. Arthur Harris for his help and permission to use the clinical material of the Bethlem and Maudsley Day Hospitals.

² Formerly Registrar Bethlem Royal and Maudsley Day Hospitals; Consultant, Psychopathic Unit, Balderston Hosp., Newark Notts, U.K.

velopment of the Maudsley and Bethlem Royal Day Hospitals. Admission criteria are those appertaining to inpatient beds, and attendance 5 days a week is obligatory. Harris suggests that speedier treatment may be possible in day hospitals, owing to the patient remaining in his home surroundings.

In Nigeria, Lambo(16) has adapted the day hospital idea to an African community and uses a day centre with night foster homes. He uses both insulin coma treatment and ECT.

The first day hospital in Russia started in Moscow in 1932(11). Day hospitals were considered as departments of mental hospitals and where the latter were overburdened were intended to take on all their functions. The Moscow day hospital treated 1,225 patients in 4 years, 47% having schizophrenia, 30% neurological diseases including taboparesis, but only 6% with manic-depressive psychosis. Practice and results were further reviewed after 12 years (12).

DIAGNOSTIC CATEGORIES OF PATIENTS TREATED

This can be illustrated by figures drawn from published data, analysis of patients treated at the Maudsley Day Hospital over a 3 year period and personal communication from Bierer and the South West Regional Hospital Board.

Diagnostic usage almost certainly varies between countries, but it is clear that day hospitals can be adapted to deal with widely different groups of mentally ill patients. In England depressive illnesses account for a considerable proportion of those treated.

ENGLISH DAY HOSPITAL PRACTICE, 1956

Enquiry at the Ministry of Health revealed that at least 10 day hospitals were open in England in 1956. The author worked at the Bethlem Royal and Maudsley day hospitals. To investigate practice elsewhere, those units treating more than 10 patients daily were either visited (The Marlborough, Bristol and Oxford Day Hos-

	Dzhagarova 1937	Menninger Clinic Barnard 1952	Bristol (SWRHB) 1957	Marl- borough Day 1956	Nigeria Lambo 1956	Maudsley Day 1953-56
Schizophrenia	47%	30%	10%	35%	24%	8%
Manic-depressive psychosis	6%	7%	29%	3%	6%	25%

(Total depressive illnesses)	6%	—	73%	41%	64	64%

pitals) or discussed with their Directors (Oldham and Birmingham).

Two types were found. The Marlborough under Dr. Bierer was entirely independent. The other type was associated with a parent mental hospital: the Bristol Day Hospital under Dr. Smith, treated general psychiatric patients; at Birmingham, under Dr. Mayer Gross, there was an experimental unit treating chronic neurotic patients, many on National Assistance; the Oldham Day Hospital under Dr. Pool, was a unit in a community care programme; Oxford, under Dr. Cosin, treated mentally and physically ill geriatric patients; the Maudsley and Bethlem accepted only those who would otherwise have needed mental hospital admission.

The main group of patients admitted to day units were those for whom outpatient treatment was inadequate or unsatisfactory, but who did not require admission to the acute ward of a mental hospital. The day hospital contributed most to the reduction of inpatient waiting lists, when it accepted only patients who would otherwise have required inpatient admission, as at the Maudsley. It also functioned as an alternative to outpatient treatment when a number of part time attenders were accepted, as at the Marlborough. Most day units found it convenient to treat both those needing full time and part time treatment.

The psychoneuroses were most successfully treated at day hospital level. The majority of depressive illnesses would fall into this diagnostic group. Depressive illnesses were the major diagnostic entity for each of the English day hospitals from which figures were available. With psychoses the acutely disturbed were clearly unsuitable, but a considerable number of schizophrenic patients could be treated at day hospital level. The Maudsley accepted patients with a depressive psychosis, but none who presented immediate suicidal risks, and there were no suicides in a 3 year analysis. The acceptance of the seriously ill was found to depend upon the quality of home care available.

There was a wide measure of agreement on the methods of treatment used. A general emphasis on group activities was found, group discussions being a feature of most units. English day hospitals did

not use insulin coma therapy, although this has been used elsewhere, admission being favoured on the grounds of safety. Electroconvulsive therapy was used in all units and the practice was to have patients escorted home afterwards.

The use of transfer to a parent hospital was carefully investigated as Cameron stated that the need for transfer was "infrequent." The available figures showed that the annual transfer rate of the Menninger Day Hospital was 16%, of the Bristol 10.4% and of the Maudsley 14.7%. The last two units definitely found transfer facilities valuable. Ease of transfer to a hospital bed at short notice contributes to the safe management of a day hospital, since sudden acute exacerbations of patients' illnesses are not uncommon.

The main factors limiting the use of day hospitals seemed to be the geographical situation and the quality of home care offered by relatives. A great expansion in this field, to cover much of the country, would seem both economical and feasible.

SUMMARY

The literature on psychiatric day hospitals is reviewed and an account is given of day hospital practice in England in 1956, with respect to types of patients treated and treatment employed. It was found that day hospitals were treating a wide variety of mental illnesses, and that those treatments commonly employed in mental hospitals could also be used in day hospitals.

CLINICAL NOTES

DEANOL (DEANER) IN THE TREATMENT OF SCHIZOPHRENIA

JOSEPH A. BARSA, M.D. AND JOHN C. SAUNDERS, M.D.¹

Deanol (Deaner)² is the para-acetylaminobenzoate salt of 2-dimethylaminoethanol. It is the tertiary amine precursor of acetylcholine, and, unlike choline or acetylcholine itself, is able to pass freely across the blood-brain-barrier. The ability of deanol to increase cerebral acetylcholine has been postulated as the mechanism of its therapeutic action.

Deanol has been used chiefly as a central nervous system stimulant for mild depressions and chronic fatigue states. However, it has also been reported to be effective in chronic schizophrenics. This study was undertaken in an effort to confirm the latter results.

As a pilot study, 10 chronic schizophrenic females between the ages of 37 and 71, who had been continuously hospitalized for 5 to 27 years, were given deanol orally for 9 months in a single morning dose of 150-300 mgs. Within the first few weeks a mild stimulating effect was evident in 6 patients. They seemed a little brighter, more alert, more interested in their environment, although their delusions and hallucinations remained unaltered. However, in the subsequent months a further change slowly manifested itself in 2 patients. Their delusions and hallucinations seemed to be fading and were more difficult to elicit. It was concluded that deanol has 2 actions: a mild stimulating effect, and a moderate anti-psychotic effect (*i.e.* combats delusions and hallucinations of the schizophrenic). However, the anti-psychotic action was not as potent as that of the phenothiazines or reserpine. It was therefore decided to combine deanol with a tranquilizer containing a potent anti-psychotic effect.

Two hundred chronic female schizophrenics between 16 and 69 years of age were

selected. They had been continuously hospitalized for 3 to 27 years, 145 having been hospitalized for 10 or more years. All of the patients had been receiving tranquilizing drugs for at least 18 months with slight or moderate improvement. However, for the last 6 months they had reached a plateau and no further improvement could be detected. It was at this point that deanol was added. One hundred twelve patients were receiving chlorpromazine, 5 prochlorperazine, 70 a combination of chlorpromazine and prochlorperazine, 6 reserpine, 4 a combination of chlorpromazine and reserpine, and 3 perphenazine. The dose of these tranquilizers was not changed when deanol was added. Deanol was given in a single morning dose of 25 to 100 mgs., the majority of patients receiving 50 mgs. Deanol in combination with the tranquilizers was continued for 6 to 13 months. At this time 84 patients were unchanged; 99 were improved, 17 being markedly improved, *i.e.*, either released or ready for release from the hospital. Of the markedly improved patients 9 had been continuously hospitalized for 3 to 5 years, and 8 patients for 7 to 19 years.

It was again observed that the clinical effects of deanol manifested themselves very slowly. It usually took several weeks for the full stimulating effect to develop, and several months for the full anti-psychotic effect. Deanol did not produce euphoria; patients became less withdrawn, more alert, interested and energetic. There were no serious side-effects. Ten patients receiving 100 mgs. complained of anorexia, and two complained of jitteriness, but these symptoms disappeared when the dose was lowered to 50 mgs. There was no interference with sleep, and no evidence of tolerance to the drug.

From this study, it can be concluded that deanol, when combined with a tranquilizer containing a potent anti-psychotic action

¹ Rockland State Hospital, Orangeburg, N. Y.
² Riker Laboratories Inc., Los Angeles, Calif.

is of definite value in the treatment of schizophrenia. Not only does its stimulating effect counteract the excessive sedation and

lethargy produced by the tranquilizer, but its own anti-psychotic effect is additive to that of the tranquilizer.

A SAFE TRANQUILIZER: NIACINAMIDE HYDROBROMIDE AS A SAFETY FACTOR

HENRY M. FEINBLATT, M.D.¹

Attempts have been made to define a tranquilizer as any sedative which accomplishes its sedation without causing a condition of areflexia. A safe tranquilizer which meets these requirements is afforded by a combination of ammonium and potassium bromides with niacinamide hydrobromide as a safety factor.² Its mild tranquilizing effect and freedom from untoward responses have made this medication the one of choice in ambulatory working individuals. The objection of bromide intoxication has been fully met by the introduction of niacinamide hydrobromide (1, 2).

Tranquilizers, both new and old, have their specific side-effects and toxic reactions. Any method of overcoming these undesirable reactions is a step forward (3). Thus, the step of utilizing niacinamide hydrobromide to overcome the side-effect of bromide medication is a definite contribution to therapy.

Bromism depends upon 3 factors: (a) bromide concentration in the blood, (b) genetic predisposition (idiosyncrasy), and (c) the co-enzyme factor (1).

The first two factors are obviously involved in any medication and the characteristic unique feature of bromism has been the poisoning effect exerted by bromides on the respiratory co-enzyme mechanism, the di- and tri-phosphopyridine nucleotides (co-enzyme I and II). Disturbance of this co-enzyme mechanism can make the person uniquely sensitive and even cause bromide intoxication at low blood concentration levels. When the essential portion of the nucleus of the co-enzymes is supplied in the form of a pyridine metabolite (niacina-

mid hydrobromide), bromism does not occur.

The clinical syndrome of pellagra is analogous to, and has many of the characteristics, signs, and symptoms of, bromism,—that is, the cutaneous, digestive, and nervous changes induced thereby. Pellagra is also controlled rapidly by the use of a specific source of the pyridine nucleus such as nicotinic acid (3-carboxypyridine). The acneform and other irritative lesions on the face and exposed part of the body of both pellagra and bromism are quickly cleared when this essential portion of the co-enzyme nucleus is supplied exogenously. Thus, niacinamide hydrobromide represents a safety factor in tranquilizing bromide medication.

Since the original study (1) of 50 cases, comparing the use of plain triple bromides with the niacinamide hydrobromide combination, 440 cases have been added to series. Statistics show that some manifestation of untoward effect has been present in approximately 15% of the cases. True bromism has been demonstrated in approximately 4% of the cases. The total figure of 15% has been reduced to less than 2% with the use of the niacinamide hydrobromide combination.

A typical case study was that of a married woman, age 28, who was treated alternately with bromides and phenobarbital for relief of extreme nervous tension. In response to either medication the patient exhibited an acneform rash covering the whole body and causing pruritus at multiple sites. When the medication was withdrawn, the rash disappeared. It was found that the niacinamide combination with ammonium and potassium bromides prolonged the therapeutic effect and also prevented the rapid development of the untoward response.

¹ 150 Woodruff Ave., Brooklyn 26, N. Y.

² Natran tablets containing ammonium bromide 250 mg., potassium bromide 250 mg. and niacinamide hydrobromide 10 mg. supplied by the John Winters Co., 313 East 53rd St., New York 22, N. Y.

The appearance of pellagra-like symptoms with rapid clearing when the co-enzyme pyridine nucleus was supplied demonstrates clinically the mechanism of interference with the enzyme oxidation mechanism of the body economy by such substances as phenobarbital and bromide. Other newer types of sedatives gave similar results.

In summary, clinical and laboratory evidence suggests that tranquilizers, including the bromides, can interfere with the co-enzyme system causing the pellagra-like syndrome. There has been abundant clinical evidence that these symptoms are re-

versed in 87% of cases and the response has been to clear up 50% of the small group exhibiting actual bromism, when the combination of ammonium and potassium bromides with niacinamide hydrobromide as a safety factor has been used as a tranquilizer.

INPATIENT TREATMENT OF DEPRESSIVE STATES WITH TOFRANIL (IMIPRAMINE HYDROCHLORIDE)¹

W. KEUP, M.D., A. APOLITO, M.D., L. OLINGER, M.D.,
M. SCHWARTZ, M.D., AND E. YACHNES, M.D.²

In 1957 Kuhn(1) published his first results with the new anti-depressive drug Tofranil³ (G-22355, imipramine hydrochloride), which turned out to have no monoamine oxidase (MAO) inhibiting effect, in contrast to iproniazid and its new and less toxic followers. Differences in the clinical actions of Tofranil and the MAO inhibitors are supposed but not sufficiently elaborated.

As a first step we therefore studied the action of Tofranil alone in a series of 66 hospitalized unselected depressed patients with different diagnoses, 28 male and 38 female, whose ages varied between 25 and 72 years. The majority of the depressions were endogenous (28 involuntal, 11 manic depressive), while 17 schizophrenic patients with depressive features and 10 patients with arteriosclerotic, senile or psychoneurotic depressions were also included. About one-third of all these cases were chronically depressed patients, some of whom had received ECT, insulin thera-

py, and different tranquilizing drugs without effect.

The drug was given by oral administration only, starting usually with a dosage of 75 mg. per day which was increased slowly to a mean dosage of about 200 mg. per day, adjusted individually. In some cases higher doses up to 400 mg. per day were used. It is believed that prolonged treatment with a low maintenance dosage is necessary to prevent relapses(2, 3). We used long term treatment, up to 5 months.

Best results were seen in endogenous depression, confirming findings of other authors(1, 4, 5). In this group, 10 patients (26%) recovered, 22 (56%) showed moderate to good improvement and 7 were unchanged. Schizophrenic patients did not respond as well, 10 remaining unchanged and 7 showing moderate or good improvement. The mixed group was also less responsive with 4 patients out of 10 showing some degree of improvement. The overall results showed that 65% of all patients treated manifested some degree of favorable response, with 17% total recovery. While these figures are lower than those reported by some previous investigators(4), the improvement rate in our cases of endogenous depression, 80%, is quite in line

¹ Preliminary note on a paper read at the Downstate Interhospital Conference, New York, April 6, 1959. Will be printed in full in J. Nerv. Ment. Dis.

² Brooklyn State Hospital, Brooklyn 3, N. Y.

³ Kindly supplied for this study by Geigy Pharmaceuticals, Ardsley, New York

with previously reported data.

From the standpoint of symptoms affected, best improvement was seen in affective depression, flow of psychological activity and alteration of thought process. Some patients showing overall improvement in the depressive state, nevertheless had worsening of one or two symptoms. In 9 patients impending or manifest agitation was observed, mainly with higher doses. In 8 of these patients, this agitation was controlled by administration of a tranquilizing drug (Thorazine, reserpine).

Other side effects observed were minor and consisted of dizziness, 3 patients, nausea, 1, blurred vision, 2, perspiration, 2, dry mouth, 2, and constipation, 2. A slight drop in blood pressure was observed in a few patients, but in some of our elderly patients this was actually a desirable side effect but not a constant one. Some of these side effects were seen only during the onset of treatment and disappeared as therapy continued. This was true for a slight tremor of the hands in 6 patients, but we observed no other extrapyramidal symptoms.

Improvement can be observed as soon as

the first or second day in some patients, but sometimes it takes 2 or 3 weeks. According to our experience, the patient who does not respond during the first 3 weeks, will not respond at all.

From the above we can conclude that Tofranil is the most potent antidepressive drug available at the present time, comparable in effectiveness with electro-shock therapy. While ECT may still be preferred in acute suicidal patients, it is our impression that this drug reduces the need for ECT drastically.

NEGATIVE RESULTS IN THE TREATMENT OF DEPRESSION WITH IMIPRAMINE HYDROCHLORIDE (TOFRANIL)

FREDERICK LEMERE, M.D.¹

A number of reports from Europe and several from America have been enthusiastic regarding the effectiveness of imipramine hydrochloride (Tofranil, Geigy Pharmaceuticals) in the treatment of depression. My own experience with this drug in 137 private patients over a 2 year period has been disappointing. These were all cases in which depression was the most prominent symptom and most of them were of the endogenous type.

The dosage used was from one to two 25 mg. capsules q.i.d. for 3 or 4 weeks provided the patient could be persuaded to take the medicine that long. The size

and duration of medication were frequently limited by unpleasant side effects or failure of beneficial results. None of the side effects was serious but dizziness, dry mouth, blurred vision, increased tension and perspiration often caused the patients to discontinue this drug.

Only 22 of the 137 thought that imipramine was of help and their initial enthusiasm usually waned as the medication was continued. No patient has asked to or was interested in continuing this drug beyond the first trial month. The evaluation of the pharmacological treatment of depression is especially difficult because most of these cases are self limited anyway and whatever is being given at the time of recovery is credited with the cure. This is especially

¹ From the Department of Psychiatry, University of Washington School of Medicine, Seattle, Wash.

true where it is recommended that the drug be given for at least a month before judging its effect.

In view of reports of success with this

drug by others, it would seem advisable to continue clinical trials, especially control studies, but my own experience so far has been disappointing.

A MODIFICATION OF THE FORREST TEST FOR PHENOTHIAZINES

JACK J. HEYMAN, M.S., M. ALMUDEVAR, M.D., AND SIDNEY MERLIS, M.D.¹

The routine determination of phenothiazines in urine samples has been thoroughly investigated by Forrest (1-2) and separately by Pollack (3). In our laboratory we modified the procedure to obtain more stable color development and at the same time preserve the simplicity of the Forrest method.

MATERIALS

A sulfonic acid resin impregnated paper SA-1 or SA-2² was further prepared by immersing strips 7" x 3/4" in filtered 2% ferric chloride solution (2g FeCl₃/100 ml. H₂O). The paper was blotted dry with clean paper towelling and oven-dried at 80° C. The prepared paper is stable.

METHODS

A drop of urine from a morning sample was placed on the paper and one drop of 15% sulfuric acid placed in the center of the ring formed by the sample drop. A violet colored ring develops in the presence of metabolized phenothiazine. The color intensity observed is constant in intensity for

each individual patient on a constant drug intake. The drug intake can be graded (Table 1) by the intensity of color observed

TABLE 1
GRADING OF THE RESULT

Grade	Dose In Mg./Day/Pat.	Color
0	0-50	yellow
plus/minus	50-75	faint pink
1 plus	50-100	violet or red
2 plus	150-600	dark violet or red
3 plus	600-900	very dark violet or red
4 plus	Overdose	extremely intense, one or more rings, violet and red.

or by diluting the sample with distilled water and testing a 1:1 serial dilution. The last positive tube number is recorded for the particular patient at the dose given. If the dose is changed, the color intensity changes, and the number of positive tubes change.

The same procedure can also be used as a toxicological aid. With gastric juice the unmetabolized phenothiazines give red coloration while the urine will show an intense violet, red or both colors. By making a serial dilution, the quantity present can be estimated (Table 2).

Running the same dilutions with a known phenothiazine until a negative result is

TABLE 2
DILUTIONS OF SPECIMENS

Tube #	0	1	2	3
ml. of Sample	1 ml. urine or gastric juice	1 ml. urine or gastric juice	1 ml. of #1	1 ml. of #2
ml. of Diluent	—	1 ml. of H ₂ O	1 ml. of H ₂ O	1 ml. of H ₂ O
Fraction of original Concentration	1	1/2	1/4	1/8

¹ From the clinical facilities and research laboratory of the Research Division, Central Islip State Hospital, Central Islip, N. Y.

obtained gives the "approximate minimum detectable quantity" (AMD). Several observed values are listed as follows :

Drug	AMD mg./ml.
Thorazine	.031
Sparine	.015
Compazine	.031
Vesprin	.031
Pacatal	.031

The approximate amount present is calculated by the equation :

$2^n \times \text{AMD} = \text{quantity present.}$

Where n=# of the tube in 1:1 dilution series

AMD=Approximate minimum detectable quantity.

CONCLUSIONS

This test has several advantages over

the Forrest Method. The color developed is fairly stable, with only slight fading observed in 24 hours. As little as one drop of sample is sufficient for grading the quantity of phenothiazine present. Therefore, the test can be used with samples from incontinent patients. A close estimation of overdoses can be made. The test retains the good qualities of the Forrest Method : it is rapid, sensitive and does not give false positives. All the phenothiazines tested gave positive results when the dose level was above 50 mg. daily.

AMINO-GLUTETHIMIDE IN THE TREATMENT OF CHRONIC PSYCHOTIC EPILEPTICS

G. DONALD NISWANDER, M.D. AND ISMET KARACAN, M.D.¹

A glutarimide derivative, glutethimide, known for its sedative properties, was observed to have an additional anti-convulsant activity when used in the treatment of epileptic patients(1). Consequently, attempts were made to find other glutarimides with anti-convulsant activity, but without sedative effects. A compound, known chemically as a-(p-amino-phenyl)-a-ethyl glutarimide, hereafter referred to as amino-glutethimide,² was discovered to have a good anti-convulsant activity without the sedative side effect.

Lambros has previously reported his experience with amino-glutethimide in a group of epileptics treated as outpatients (2). Eighty per cent of Lambros' patients improved, in terms of a decrease in number of seizures while receiving the medication. Sheehan has mentioned his experience with

this compound, but he does not give results obtained with it(3).

Below are the results of 9 months experience and observations in the use of amino-glutethimide for the treatment of chronic hospitalized psychotic epileptic patients.

METHOD OF STUDY

Twenty-five female and 13 male patients were selected on the basis of the diagnosis "chronic brain syndrome associated with convulsive disorder, with psychotic reaction." Age range was from 25 to 76 years, with a median age of 40 years. The duration of hospitalization extended from 4 to 35 years, with a median duration of 10 years. Each of the patients was receiving either phenobarbital or diphenylhydantoin alone or in combination previous to the study. Initially each patient was given either 125 mgs. or 250 mgs. of amino-glutethimide daily. This dosage was increased by this same amount every 5 days until a therapeutic level of the drug was reached of between 750-2,000 mgs. daily. When amino-

¹ Arthur P. Noyes Institute for Neuropsychiatric Research, New Hampshire State Hosp., Concord, N. H.

² The amino-glutethimide used in this study was supplied as Elipten by the Ciba Pharmaceutical Products, Inc., Summit, N. J.

glutethimide was prescribed, the other anti-convulsants were gradually withdrawn over a 4 week period. Blood pressures, blood counts, and urinalyses were evaluated periodically during the study. Grand mal seizure frequency had been carefully recorded before the study, and this was continued during the experiment.

RESULTS

The withdrawal of previous anti-convulsant medications after prescribing amino-glutethimide was successfully carried out in all but one female patient, who developed status epilepticus. After this condition was controlled, the compound, in combination with the previous medication, was re-prescribed resulting in fewer seizures. In other patients who had more seizures, the diphenylhydantoin sodium and/or phenobarbital sodium were re-prescribed in reduced dosage levels with better seizure control.

In regard to control of grand-mal seizure frequency, amino-glutethimide is an effective anti-convulsive medication, used either alone or in combination with other anti-convulsants.

In the last 5 months of the study, after stabilization of this epileptic group, grand-mal seizures were reduced 25-35% compared to seizure frequency before the project began.

At the beginning of the study, 2 patients

(5.3%) developed a macular rash which was more prominent on the extremities. The rash disappeared within 4 days after the medication was discontinued. Each of these patients had begun receiving 250 mgs. of the compound daily, which had been increased 250 mgs. on the fifth day. None of the patients who initially started on the smaller dosage of 125 mgs. developed a rash. In view of this observation, patients added to the study thereafter were started on the smaller dosage; no further skin reactions have occurred.

Two patients receiving 1,500 mgs. of amino-glutethimide daily complained of nausea. Two patients receiving this amount of the drug were observed to have a staggering gait and unsteadiness while standing. When the dosage was reduced to 750 mgs. all of these symptoms subsided. These side effects from amino-glutethimide observed in this study are in accordance with what other investigators have reported. Drowsiness was not observed as a side effect. No significant changes were found in blood pressures, urinalyses, and blood counts.

CHEMOTHERAPEUTIC TRIALS IN PSYCHOSIS : III. ADDENDUM 2-Brom-d-Lysergic Acid Diethylamide (BOL)

WM. J. TURNER, M.D., MANUEL ALMUDEVAR, M.D., AND
SIDNEY MERLIS, M.D.¹

In a previous communication(1) we have reported : "BOL-148 administered to chronic schizophrenics, 1 mg. t.i.d. to 6 subjects for 2 weeks, or 5 mg. q.i.d. for 3 days to 3 subjects, had no evident effect on their psychoses." Subsequently the work of Schneekloth, Page, del Greco and Corcoran(2) led us to consider whether we had used doses too small to demonstrate any therapeutic action. Accordingly, 6 schizophrenic women were included in a

further study. These patients had been on our Research Ward for periods up to 18 months. With each of them we had excellent rapport, and the transference reactions of dependency, and their expectation that they would be saved was quite clear. Three of them were known to be hallucinating most of the time. All had extreme feelings of guilt and were withdrawn except under favorable situations, with a person to whom they had become attached.

Each subject received a dose of LSD, 75 gamma, preceding the start of BOL

¹ Research Division, Central Islip State Hospital, Central Islip, N. Y.

medication. The LSD clearly brought out in each instance a psychic disturbance, with agitation, anxiety with exacerbation of the helpless dependency needs, or defensive hostility. Their experiences were described in such terms as "inability to stop memories," "something happening to me," or: "What was in that glass? I can't think right."

All patients were started on 10 mg. of BOL 3 times a day.² One patient had such a degree of alarm and agitation on this dose that she was reduced to 1 mg. daily for the first week. Several of the other patients commented on the fact that the first morning dose made them feel very jumpy and rather fearful that they might break down, for instance, from a "cool, distant reserve." Medication continued for a minimum of 4 weeks; 2 patients continued for 5 weeks. On their last day 4 of the patients received 1 mg. of BOL plus 150 or 200 gamma of LSD. The other 2 patients had no BOL for 18 hours preceding LSD 150 gamma and 200 gamma respectively. In all 6 instances the response to LSD was completely absent.

Interviews, observations of behavior and subsequent descriptions by 4 of the patients confirmed our impression that no change in attitude had taken place under the action of BOL. Hallucinations, when present before, were of the same intensity and quality at the end of the BOL experience. Hostile aloofness, anxiety, withdrawal, feelings of hopelessness, of injustice, of ultimate submissiveness, of bewilderment and perplexity, all remained unchanged.

COMMENT

The work here reported is part of our effort to clarify and if possible to define the role of biochemical factors in the pathogenesis of schizophrenias. One aspect of this is a widely accepted assertion that LSD produces a "model psychosis," a model, so to speak, of schizophrenia. In the face of the data which have been published in support of this assertion our limited data and personal experiences must carry little weight but, for what it is worth, we do not agree. Some of our reasons have been stated by or are implicit in the data

of other workers (Hoch(4), Levin(5), Stoll(6), Bleuler(7)). To these we would add one not previously reported, to our knowledge: our patients who were able to communicate told us that the LSD experience was not the same as their psychotic experience.

It might be objected that we have not shown conclusively that the LSD reaction was completely blocked. The difficulties in doing a formal study of psychotic subjects under LSD are well known. The rarity with which the psychotic subject reports the visual disturbances which play so prominent a part in the reaction of non-psychotic subjects is also well known. When these difficulties are combined, we feel that the best means of testing the LSD reaction is to compare one patient with herself at different times. Since we have done this, we believe that we are justified in claiming that the reaction to as much as 200 gamma of LSD was completely blocked by BOL. It is of theoretical importance that the abolition of the LSD reaction may occur without interfering with the patient's pre-existing psychosis.

SUMMARY AND CONCLUSIONS

BOL in doses of 10 mg. orally 3 times daily for 4 to 5 weeks was administered to 6 chronically ill schizophrenic women. This abolished the response to LSD up to 200 gamma but failed to alter the psychosis in any way. Initial doses of 10 mg. BOL may produce mild LSD-like reactions.

COMMENT

STATISTICS AND STATISTICIANS : A TIMELY WARNING

WERNER TUTEUR, M.D.¹

Scientific claims should be judged on experimental evidence rather than on plausibility and conformity, Hopkins warned recently. He added that the practitioner of psychiatry is leaning on a weak reed if he depends merely on the findings of specialized research workers. Psychiatric research, he states, is starving to death for want of ideas, space, mature and well trained personnel(1).

Statistics, euphemistically considered reliable sources of information, may at times be confirming, confusing or misleading. New methods of treatment usually are evaluated with "true statistical facts," allegedly proving the point in question. Frequently one is deluged by numerical data of clinical studies, most of them, no doubt, representing well motivated and honest work, many showing the most sophisticated and elaborate detail. At such occasions one does well to remember some examples of basic fallacies inherent in statistics and statisticians. They show how loosely certain concepts can be used and the false security on which conclusions are sometimes based.

For many decades it has become a popular slogan that every other hospital bed in the United States is occupied by a mental patient. This is perfectly true for a given day in the calendar year, but it does not mean that mental illness prevails among half of all hospitalized patients. Many are the times when one hears this "every other bed" slogan during campaigns, lectures and addresses by lay persons as well as those belonging to our ranks. The fact is frequently overlooked that the same general hospital bed is used throughout the year by a large number of patients with physical illness, that the general hospital turnover in no way compares with that of a mental hospital and that thus the general distribution of morbidity is entirely removed from the fact that "half of all hospital patients are mental cases."

Per diem rates prevailing in State and Government operated institutions are a favorite subject regarding "better care for the mentally ill." Easily the conclusion is reached by the uncritical that the agency showing the highest *per diem* rate gives the best and the one with the lowest, the worst, care to its patients. Completely overlooked is usually the fact that *per diem* rates by necessity are derived from the most varying basic circumstances. At the Ninth Mental Hospital Institute held at Cleveland, Ohio, this subject created a lively discussion headed by Blasko(2). Among many other issues the following highlighted the debate. States located in moderate climates spend little on fuel, while those exposed to inclement weather sometimes do so in excess. Food prices vary from state to state and are to a large measure dependent on the market value of home grown products, rendering the *per diem* rate low. Union wages for crafts vary across the entire country, once more introducing a variable into the *per diem* rate which has absolutely no bearing on psychiatric care.

Much inaccuracy prevails statistically on the matter of suicides. The drop of suicides during wartime is allegedly an "established fact." Evidence shows that this is erroneous. Raines speaks of concealed suicides occurring in the Armed Forces during war(3). The unaccounted number and the unknown motivations of men volunteering for dangerous missions, almost always representing a great risk of death and ending fatally, falls into this category. Or, soldiers landing on a beachhead walking into a mine field and promptly being blown apart, ignoring warning signs "as large as box cars," likewise seem to indicate successful suicidal attempts never covered statistically.

The very interesting phenomenon of physiological suicide(3) escapes statistical evaluation completely. Here belong hitherto well balanced diabetics who wilfully become unmanageable, slip into coma or

¹ Clinical Director, Elgin State Hospital, Elgin, Ill.

shock to die, cardiovascular patients who discontinue their medicinal regimen and become otherwise uncooperative with the overt or covert wish to die, and many others.

These are only a few examples of statistical looseness, of poorly disciplined and faulty thinking, leading to erroneous conclusions. Such thinking makes for scientific detours, for inaccuracy, of which psychiatry is replete already, since human data *per se* are qualitative, frequently sparse and mostly subjective. To this should be added the physiological margin of error inherent in most clinical work, rarely mentioned public-

ly, for which allowance is hardly ever made. Only after diligent filtering will statistics—without which we could not do—avail themselves for proper interpretation.

"I respect faith, but it is doubt that gets you an education" was said once by Wilson Mizner.

EDUCATION

Education, in short, cannot be better described than by calling it *the organization of acquired habits of conduct and tendencies to behavior.*

—WILLIAM JAMES

VERITAS

Marxism a science ? I don't know a movement more self-centered and further removed from the facts than Marxism. Every one is worried only about proving himself in practical matters, and as for the men in power, they are so anxious to establish the myth of their infallibility that they do their utmost to ignore the truth.

—PASTERNAK
(Dr. Zhivago)

CORRESPONDENCE

DR. SAMUEL W. HAMILTON AND THE FOUNDING OF THE AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY, INC.

Editor, THE AMERICAN JOURNAL OF PSYCHIATRY :

SIR : In the March issue of the American Journal of Psychiatry I was interested in reading the article on "The Founding of the American Board of Psychiatry and Neurology," established as a result of the conference held under the auspices of the Division of Psychiatric Education of The National Committee for Mental Hygiene, Inc. (now The National Association for Mental Health, Inc.).

There is one name missing among those credited with the preparatory work of this Board, and if the authors (and the readers, too) were not aware of his participation it was due, I am sure, to his self-effacement. That person was the late Dr. Samuel W. Hamilton.

In 1933 at the time preparations were being made to call this conference, Dr. Hamilton was the Acting Director of the Division of Psychiatric Education of The National Committee for Mental Hygiene. It was he who gathered the directories of the medical specialty boards then in existence as sam-

ples and prepared the materials used in the discussions at the Boston conference in May, 1933. It was he, too, who made the arrangements for this conference and invited the participants.

Perhaps one should mention also, in this connection, the late Paul O. Komora (Assistant Secretary of The National Committee for Mental Hygiene), who for 25 years worked closely with the American Psychiatric Association on various projects and was present at the first conference on psychiatric education, at which the desirability of the establishment of a specialty board in psychiatry and neurology was discussed. To Mr. Komora we are indebted for the excellent report of that meeting which is listed in the references at the end of the article "The Founding of the American Board of Psychiatry and Neurology."

Emily L. Martin,
(formerly Executive Secretary,
Division of Psychiatry Education,
The National Committee for
Mental Hygiene, Inc.)

REPLY TO THE FOREGOING

Editor, THE AMERICAN JOURNAL OF PSYCHIATRY :

SIR : On behalf of my co-authors I wish to make amends for the oversight in omitting the name of Dr. Samuel W. Hamilton from those who contributed to the founding of the American Board of Psychiatry and Neurology.

None of us attended the important Conference on Psychiatric Education May 28

and 29, 1933, but Dr. Hamilton's remarks upon that occasion brought the whole problem into focus. We are gratified that Miss Martin has brought Dr. Hamilton's contribution to the notice of both ourselves and of the readers of the American Journal of Psychiatry.

Walter Freeman, M.D.,
Los Altos, Calif.

HYPERTENSION DUE TO CHLORPROMAZINE

Editor, THE AMERICAN JOURNAL OF PSYCHIATRY :

SIR : With reference to the case report entitled "Prolonged Hypotension due to Chlorpromazine" by Dr. W. J. Stanley, in the June 1959 issue of The American Journal of Psychiatry, I believe that another blood pressure reaction related to chlorpromazine treatment should be looked for because of its possible hazards. This reaction is hypertension following administration of chlorpromazine.

Dr. Nathan Beckenstein, Director of the Brooklyn State Hospital, informed me that a drastic rise in blood pressure has occurred in young, ordinarily normotensive, male patients approximately 4 hours subsequent to an intramuscular injection of as little as 50 mgm. of chlorpromazine. This apparent withdrawal type response was noted in studies done at the Brooklyn State Hospital some time ago.

Recently I have had occasion to treat a 62-year-old white married man with chlorpromazine by mouth for an involutional psychotic reaction. This patient had a

coronary occlusion several years before, had been a known hypertensive, and had suffered from angina pectoris until approximately 3 years prior to my seeing him. After he had improved considerably from psychotic symptoms, chlorpromazine (50 mgm. q.i.d.) was discontinued. Within the 24-hour period following, the patient became nauseated, and EKG showed recurrence of an arrhythmia. The internist who treated him reports that the patient was again placed on chlorpromazine with improvement of nausea and cardiac symptoms.

Dr. Beckenstein's experience, and mine with this patient, suggest that subsequent to the administration of chlorpromazine, a pronounced hypertension may occur which could be disastrous to those with pre-existent cardiovascular disease.

The purpose of this letter is to call this to the attention of those who may have similar observations or who desire to investigate the cardiovascular effects of chlorpromazine withdrawal.

Edward L. Pinney, Jr., M.D.,
Brooklyn, N. Y.

STYLE

Cultivate simplicity, Coleridge, or rather, I should say, banish elaborations ; for simplicity springs spontaneous from the heart, and carries into daylight its own modest buds and genuine, sweet, and dear flowers of expression.

—CHARLES LAMB
(in a letter to Coleridge Nov. 8, 1796.)

MATHEMATICS AND REALITY

In my opinion the answer to this question is briefly this : as far as the laws of mathematics refer to reality, they are not certain ; and as far as they are certain, they do not refer to reality.

—EINSTEIN

HISTORICAL NOTES

BI-CENTENARY OF THE BIRTH OF VINCENZO CHIARUGI (1749-1820) A PIONEER OF THE MODERN MENTAL HOSPITAL TREATMENT

GEORGE MORA, M.D.¹

The picture of psychiatry at the beginning of the 19th century, as described by Kraepelin in a little remembered, but significant book,² is very important. The verbal description and the pictorial reproduction of the methods of treatment in use at that time—from cruel strait jackets and other torture-like devices to isolation in filthy cells, from rotatory machines to complicated systems of sudden baths—leaves one today with a feeling of disgust and sadness. Yet, these methods were in use only a century and a half ago—and they had to continue through the first decades on the 19th century—at the time when a long tradition of Christian ethics and a more recent one of scientific progress had established their strongest roots in the Western European thought.

At the height of the Enlightenment, centuries after the fore-running modern view-

point on treatment of mental patients as expressed by Aretaeus and Soranus³—not to mention the Arabian humanitarian approach and the "Renaissance" psychiatry of Weyer⁴—at the time of the greatest enthusiasm for human knowledge, not only in the scientific but also in the "humanistic" fields, from medicine to sociology and jurisprudence, the general attitude toward mental patients was still characterized by mistrust, suspicion, horror, and cruelty. Others⁵ have attempted to clarify this unconscious fear toward mental patients, which accounts for such an irrational attitude, a fear which seems almost paradoxical at the time when rationalism prevailed.

Certainly, no matter how strong these prejudices dictated by fears must have been, some signs, harbinger of a new approach to mental diseases, were already present. The importance of "passions" for the understanding of human psychology, a concept introduced by Descartes in 1649, started to appear in some of the most important writings of physicians of the time,

¹ Director, Out-Patient Department, Bradley Hospital, East Providence, R. I.; Research Assistant, Department of the History of Medicine, Yale School of Medicine.

² E. Kraepelin: *Hundert Jahre Psychiatrie*, Berlin: Springer, 1918. Kraepelin summarizes the situation of psychiatry at the beginning of the 19th century in these terms: "Disregard for and crude treatment of the mentally sick, lack of appropriate physical facilities and medical care, uncertain and strange ideas on the causes and essence of insanity, torture of patients through meaningless and at times extravagant means of treatment. It would certainly be unfair to expect that the above mentioned factors could result in progressive developments. It is true that then and even earlier there were individual places in which patients were treated well and properly. There were even physicians who achieved a better understanding of mental disturbances by their rich experience and natural ability and who, endowed with a serene viewpoint and a warm approach, followed the right direction in the treatment of their patients. These exceptions alone, however, could not decisively influence the general state of scientific knowledge and the destiny of large masses. They were only the seeds, from which, under the most favourable circumstances, the science of psychiatry could develop in the following century." (p. 68)

³ Aretaeus and Soranus, both active in medicine toward the end of the first century A.D., introduced a very humanitarian approach in the treatment of mental diseases, as related by Caelius Aurelianus in his works *On Acute Diseases* and *On Chronic Diseases* (5th century A.D.).

⁴ Johann Weyer, or Wier (1515-1588), the most well known among a number of authors who fought the belief in witchcraft in the late 16th and early 17th centuries, wrote the important book *De prestigiis daemonum* in 1563. He is currently considered as the first pioneer of psychiatry. The humanitarian approach to mental diseases, as applied in some Islamic countries around the 15th century, still remains largely unknown today. It contains many elements, however, similar to those pursued by modern psychiatry, as can be seen in the recent study by J. E. Stahelin: *Zur Geschichte der Psychiatrie des Islams*, Schweiz. med. Wchnschr., 87: 1152, 1957.

⁵ G. Zilboorg, *A History of Medical Psychology*, New York: Norton, 1941, passim; A. Gregg: *A critique of psychiatry*, Am. J. Psychiat., 101: 285, 1944.

from George Stahl (1702) to Boissier de Sauvages (1771) and Clément Tissot (1798).⁶ Parallel to a timid pre-romantic trend in the 18th century philosophy and literature, an initial trend toward a more comprehensive attitude toward human beings, even in their irrational expressions, began to manifest itself sporadically in the vast, and cold, nosographic structures of medical writers.⁷ The synthetic effort evident in the all-comprehensive medical and philosophical systems of the 18th century could not completely overshadow a genuine interest for the individual and his problems.

This trend was also present in psychiatry, where some isolated individuals—under the influence of the English philosophy and of the French Enlightenment—started to question the validity of the cruel treatment to mental patients. While the need for reforming the treatment to mental patients was strongly expressed by Jacques Tenon (1788) and by Jean Colomblie (1789), a more humanitarian, but still pre-scientific approach toward mental diseases was already applied at the Charité de Senlis in Paris,⁸ as well as in similar places. So far, however, official medicine had remained absent from this movement. Strangely enough, the first decisive step toward a scientific reform in psychiatry occurred in Italy, a less progressive and “enlightened” country than France and England.

The evaluation of the cultural situation of the 18th century European countries is a matter of recent investigation, as such an evaluation has been traditionally limited to France and England. The general characteristics of Italian Enlightenment, essentially an integration of the cultural movement by the political absolutistic element with emphasis on concrete and practi-

cal aspects, have been brought into focus only recently. Of the several states in which Italy was divided in the second half of the 18th century, these renewing currents were especially evident in Lombardy in the field of public administration, in the kingdom of Naples in the field of jurisprudence and economy, and in Tuscany in the field of politics and social welfare. It is especially to the cultural scene of Tuscany during the rule of the Grand Duke Pietro Leopoldo (1747-1792), that modern historians have turned their attention. The importance of the series of reforms affecting all the areas of the state's life, economic, financial, judicial, educational and social during his 25 years of ruling, from 1765 to 1790, have been emphasized by many.

A chemist himself, Leopold was a fervent admirer of the social ideas brought to Italy by the English and French Enlightenment. He introduced the *Encyclopédie* in Italy in 1758, permitted the publication of important social and legal works (such as Cesare Beccaria's *On Crime and Punishment*),⁹ and surrounded himself with scientists and skillful physicians who brought reputation to the universities of Pisa and Florence, in line with the tradition inaugurated by Galileo two centuries before. As a completion of such an important program of reforms, the Grand Duke Leopold and his collaborators elaborated in detail a project for a political constitution—similar in its general philosophy to the first Constitution of Virginia of 1776—which unfortunately could not be put into effect because of the departure of the Grand Duke for Vienna to become emperor in 1790. Even admitting that such a project was far above the capacity of comprehension of the population so to raise opposition rather than support, the judgment of the historians is unanimous in indicating in Pietro Leopoldo the most progressive ruler that Italy ever had and in his peaceful reforms the application of the democratic principles which had to wait for 30 years more—after the horrors of the French revolu-

⁶ George Stahl (1660-1734), Boissier de Sauvages (1706-1767) and Clément Tissot (1750-1826), well known physicians of their time, all emphasized the influence of emotions on mental and physical diseases, anticipating many views presented later.

⁷ Among the attempts to classify physical as well as mental diseases in a comprehensive system, the most important remain those by Boissier de Sauvages (*Nosologie methodique*, 1771), by William Cullen (*First Lines of the Practice of Physick*, 1777 and *Treatise of the Materia Medica*, 1789), and by Erasmus Darwin (*Zoonomia*, 1794).

⁸ H. Bonnafous-Sérieux: *La Charité de Senlis*, Paris, Presses Univ. de France, 1936.

⁹ Cesare Beccaria (1738-1794) acquired an international renown through his work *On Crime and Punishment* (1764), translated in many languages, in which he made a plea for moderating punishments and for abolishing confiscation, torture and capital punishment.

VINCENZO CHIARUGI

(1759 - 1820)

tion—to be finally formulated in the French constitution.

Among the decisions taken by the Grand Duke were the abolition of the torture and death penalty for severe offenses, which culminated in the public destruction of the torture tools in 1782, and the foundation of a special institution for the rehabilitation of juvenile delinquents. An event even more important than these, but unfortunately almost universally overlooked by historians, is the foundation of the Hospital Bonifacio in Florence in 1788, entirely dedicated to the care and treatment of about 125 mental patients.

Vincenzo Chiarugi, a brilliant young physician, born near Florence in 1759, and graduated from Pisa in 1780, was put in charge of this new hospital. The following year, 1789, Chiarugi published the *Regulations of the Hospital Bonifacio*, which contain the foundations for the treatment of mental patients and which anticipated the philosophy of "moral treatment" of the following decades in Europe as well as in this country.¹⁰ On the basis of the experience accumulated in some years of intensive work at the hospital, Chiarugi published in 1793-1794 his main work, in 3 volumes, *On Insanity*, which constitutes today a very rare bibliographical item.¹¹ Following this, in 1802, he was appointed professor of dermatology and mental diseases at the newly established medical school of Florence, and later on he became professor of physiology, pathology and materia medica. He died in 1820.

In his work *On Insanity* Chiarugi makes a strong plea against the old belief concerning mental diseases as due to possession

by evil spirits and tries to base his statements only on scientific observations. The psychological foundations of the individual are still largely based on a combination of Aristotelian-tomistic philosophy with cartesianism, a view which he supports by following many students of the nervous system of the 16th and 17th centuries. In spite of the fact that passions are given importance ("between passions and insanity there is only a difference of degree and duration"), he considers insanity as an "impairment of the physical structure of the brain." As a true follower of Morgagni, each case described contains a summary of the history, of the clinical manifestations and at times of the pathological findings.

He presents a division of insanity in three major categories: (a) melancholia (b) mania (c) amentia, a classification which was essentially followed in other books, including Pinel's treatise. *Melancholia* (true, false, or violent) is characterized by "fixation of the mind on one or a few distorted ideas, while the other intellectual functions remain untouched." *Mania* is "a generalized insanity accompanied by violent and impetuous actions." *Dementia* (congenital or acquired) "is general insanity characterized by abnormal actions of both the intellect and the will, performed without any show of emotions."

Many factors both congenital and acquired are considered either as predisposing or precipitating causes of insanity, but large emphasis is also given to environmental factors. "As man's natural disposition is to imitate the actions of his associates, through education a man's character is molded, his senses develop and even his inclinations may be modified."

As far as diagnosis is concerned, "in describing the nature of insanity in general, one must first have an idea of what the essential elements are and consider the external signs and the general phenomena which accompany it." And later "there is a considerable change in the instincts and personality of a mentally ill person." Furthermore, he emphasizes the value of a careful description of the physical and emotional aspects of the patient's personality, and insists on the manic-depressive course of many psychiatric conditions.

In discussing prognosis, he states that

¹⁰ According to the historian Antonio Zobi (*Storia civile della Toscana*, Firenze, Molini, 1850, vol. 2, p. 324) these *Regulations* served as an example to improve the condition of other mental hospitals in different countries.

¹¹ The full title of this work is: *Della pazzia in genere e in specie con una centuria di osservazioni* (*Medical Treatise on Insanity, with one hundred observations*), Firenze, Carlieri, 1793-1794, 3 vols.; 2nd. ed. Firenze, Pagani, 1808. This work soon appeared in German under the title: *Abhandlung ueber den Wahnsinn ueberhaupt und insbesondere nebst einer Zeanturie von Beobachtungen*, Leipzig, 1795. Only 2 copies of the original Italian first edition are known in this country, one at the National Library in Cleveland and the other at the Yale Medical Library.

long term conditions, especially if combined with badly regulated education, have a more unfavorable outcome than conditions due to acute or physical causes.

Chiarugi's main contribution to psychiatry remains, however, in the treatment of mental diseases. After mentioning the importance of diet, of drugs, and the favourable effects of music on certain conditions, Chiarugi formulated in detail the *principles of hospital care and treatment* both in the "Regulations of the Hospital Bonifacio" and later on in his book *On Insanity*. These are the main points of his philosophy: Patients are to be admitted to the hospital only after a careful history has been obtained; a physician has to be on duty in the hospital at all times; under no circumstance should force be used on patients; temporary restriction methods are limited to the use of strait jackets and strips of reinforced cotton cloth, so as not to interfere with the patient's blood circulation; special precautions are to be taken in regard to furniture and other supplies, so as to prevent injuries; the hygienic conditions of the institution have to conform to certain basic requirements; activities for patients are to be encouraged, though only under the supervision of the physician.

As far as direct or "moral" treatment is concerned:

It is a supreme moral duty and medical obligation to respect the insane individual as a person. It is especially necessary for the person who treats the mental patient to gain his confidence and trust. It is best, therefore, to be tactful and understanding and to try to lead the patient to the truth and to instill reason into him little by little, in a kind way.

Later on:

The attitude of nurses and doctors must be authoritative and impressive, but at the same time pleasant and adapted to the impaired mind of the patient. Generally, it is better to follow the patient's inclinations and give him as many comforts as is advisable from a medical and practical standpoint.

Clearly as results from the above mentioned, Chiarugi anticipated both in theory and practice the scientific views and the reform later introduced by Pinel and his

followers in the field of mental diseases.¹² A striking similarity in both precursors, Chiarugi and Pinel, is indicated by the fact that their reforms of the treatment of mental patients could succeed only in an atmosphere of social progress and of political freedom, such as in Tuscany in the late 18th century and in France after the revolution.¹³ There is no knowledge of any other all-comprehensive and well integrated approach to mental patients previous to that of Chiarugi, so that his work constitutes a definite landmark in the history of psychiatry. It is unfortunate that statistical figures concerning the patients treated at the Hospital Bonifacio are not available and that Chiarugi's work remained interrupted at his death by a lack of a successor. Even more unfortunate is the fact that Chiarugi's name was soon forgotten in the midst of the political turmoil created by the wars of independence in Italy during the past century and that his book, written in a language not known to many, remained virtually inaccessible to many. As shown by the well-documented studies by E. Padovani¹⁴ and G. Mora,¹⁵ Chiarugi's reform was largely overlooked not only in this country, but even in Italy, by psychiatrists as well as by medical historians, up until the beginning of this century. The re-evaluation of Chiarugi's work, antedated by a famous polemic article by C. Livì in

¹² In the historical introduction to his *Traité médico-philosophique* (1801), Pinel passed a very harsh and unjust judgment on Chiarugi's work. Unfortunately, such a judgment was uncritically repeated by later psychiatrists. Actually, the similarities between the two works of Chiarugi and Pinel are striking, especially in regard to the classification of mental diseases and to the treatment of mental patients.

¹³ This consideration could be extended also to this country, where the reform of the treatment of mental patients, as introduced by Benjamin Rush and others at the beginning of the 19th century, coincided with a reform movement of the whole social life of the nation. See: A. Deutsch: *The Mentally Ill in America*, New York: Doubleday, 1937, especially Chaps. 5 and 6.

¹⁴ E. Padovani, *Pinel e il rinnovamento dell'assistenza agli alienati . . .*, Giorn. psichiatr. e neuropat., 55: 69, 1927.

¹⁵ G. Mora, Vincenzo Chiarugi (1759-1820). His contribution to psychiatry. Bull. Isaac Ray Med. Libr., 2: 50, 1954.

1864,¹⁶ officially began at the beginning of this century with the description of Chiarugi's approach to mental diseases by S. Kornfeld,¹⁷ and was followed by the beautiful essay by A. Vedrani¹⁸ and more recently

by the above-mentioned studies by E. Padovani and G. Mora. Beside this, Chiarugi's work has been recently the subject of a number of less important articles or of simple mention by some psychiatrists and medical historians. Today, at two centuries from his birth, Chiarugi's reform should be rightly commemorated as the beginning of a new era in psychiatry and his name should be given a proper place in the history of psychiatry.

PROCEEDINGS OF THE AMERICAN PSYCHIATRIC ASSOCIATION

THE ONE HUNDRED AND FIFTEENTH ANNUAL MEETING PHILADELPHIA, PENNSYLVANIA, 1959

The 155th Annual Meeting was held in Philadelphia, Pennsylvania, April 27-May 1, 1959, with headquarters at the Bellevue Stratford Hotel and business meetings and scientific sessions at the Trade and Convention Center. The opening meeting was called to order by Dr. Francis J. Gerty, President, at 9:00 a.m., on April 27. The Right Reverend William P. Roberts, D.D., former Bishop of Shanghai, delivered the Invocation; His Honor, Richardson Dilworth, Mayor of Philadelphia, gave a welcoming address to the members, followed by the introduction of Dr. William Malamud, the President-Elect, by Dr. Gerty. Dr. Mathew Ross, Medical Director, was called upon to give his first report to the membership since assuming this position. He spoke on the importance of continuing to improve methods of communication within the Association, on his plans for becoming acquainted with more of the membership, and on activities of the Central Office. Dr. Walter Obenauf, Speaker of the Assembly of District Branches, presented his report noting the enlarging scope and responsibility of the District Branches in the activities of the Association. Dr. Theodore L. Dehne, who served as Co-Chairman with Dr. Lauren Smith for the Arrangements Committee, spoke regarding the work of this Committee in handling preparations for the Annual Meeting. In his report as Chairman of the Program Committee, Dr. John Donnelly announced various aspects of the Program of special interest and stated that 174 scientific papers and 26 Round Tables composed the Program for this meeting. Dr. Lawrence C. Kolb, who had been elected by Council to the position of Secretary Pro Tempore due to the illness of the Secretary, Dr. C. H. Hardin Branch, reported that the official membership count on March 31, 1959 was 10,420. The Treasurer, Dr. Robert H. Felix, then reported

on the financial standing of the Association at the end of the fiscal year on March 31, 1959.

The Chairman of the Hofheimer Prize Board, Dr. John Nurnberger, announced that the Association's \$1,500 prize was presented this year to Irving L. Janis, Ph.D., for his research work published as "Psychological Stress: Psychoanalytic and Behavioral Studies of Surgical Patients." The 1959 recipient of the Isaac Ray Award was Dr. Maxwell Jones, the well-known British psychiatrist, who will present a series of lectures on psychiatry and the law during the coming academic year at the George Washington University in Washington, D. C. Dr. Ross announced the Nebraska Psychiatric Institute as the winner of the 1958 Mental Hospital Service Achievement Award. Honorable mention was also accorded to the Minnesota Department of Public Welfare, St. Paul, Minn., the New Jersey Neuropsychiatric Institute, Princeton, N. J., and Osawatomie State Hospital, Osawatomie, Kan. Recommendations of the Membership Committee, as approved by Council, on applications for election to membership and for changes in membership status were formally presented to the membership for vote and, on motion duly seconded, were approved as presented.

Dr. Malamud then introduced Dr. Gerty who presented his Presidential Address entitled "The Physician and Psychotherapy" in which he provided a careful analysis of the concept of psychotherapy and its place as a treatment method in medicine, including the role of the psychologist in relation to psychotherapy. Dr. Malamud was respondent. Immediately following this address, the session observed a moment of silence in memory of those members of the Association who had died since the 1958 Annual Meeting. Dr. Kenneth Appel then read a Memorial to the late Past-President

Edward A. Strecker.

The second business session was called to order by Dr. Gerty on Tuesday, April 28, at 2:00 p.m. The first item of business was a report of the results of the election of officers for 1959-60. The successful candidates were announced by Dr. John E. Davis of the Board of Tellers as follows: Dr. Robert H. Felix, president-elect; Dr. S. Spafford Ackerly, vice-president; Dr. Franklin Ebaugh, vice-president; Dr. C. H. Hardin Branch, secretary; Dr. Addison M. Duval, treasurer; incoming Councillors: Dr. Calvin Drayer, Dr. Paul Hoch, and Dr. Aldwyn B. Stokes.

Reports were presented by the Coordinating Committee Chairmen reviewing the activities of their respective groups of committees during the past year and plans for the future. Dr. Frank Curran, Chairman, reported for the Coordinating Committee on Technical Aspects of Psychiatry; Dr. Wilfred Bloomberg reported as Chairman of the Coordinating Committee on Professional Standards; and Dr. Paul Lemkau, as Chairman of the Coordinating Committee on Community Aspects of Psychiatry. Dr. Lawrence C. Kolb, Secretary Pro Tempore, then read a series of proposed amendments to the Constitution and By-Laws regarding membership in District Branches. These amendments will be presented to the membership for final consideration on the next annual ballot.

Following the completion of the business meeting, Dr. Gerty presided over the annual Convocation for newly elected Fellows at 3:00 p.m. with Drs. Lauren H. Smith and Theodore L. Dehne serving as Grand Marshals. Dr. Karl Menninger delivered the Fellowship Lecture (Academic Lecture) on "Hope," a thoughtful and stimulating examination of this powerful tool in the doctor-patient relationship.

The next business session was opened at 9:30 a.m. on Wednesday morning, April 29, by Dr. Gerty. Dr. Kolb presented the report of the Secretary outlining the major actions of the Council since the last Annual Meeting. On motion duly seconded from the floor, these matters were approved by the membership. By separate motions, Atlantic City was approved as the site of

the 1960 Annual Meeting and the Santa Clara-Monterey Psychiatry Society was approved as an Affiliate Society of the Association. Dr. Gerty then read the names of Officers, Councillors, and Committee Chairmen retiring from office at this Annual Meeting and announced that each would receive a Certificate in recognition of his service to the Association.

The Annual Dinner was held on Wednesday evening at 7:30 in the Ballroom of the Bellevue Stratford Hotel. Dr. Gerty introduced various APA officials and their wives as well as representatives of other national organizations and foreign guests. The Past-President Badge was presented to Dr. Gerty by Dr. Francis J. Braceland. The dinner was followed by dancing until 1 a.m.

The Adolf Meyer Memorial Lecture, another highlight of the meeting, was presented at 9:30 a.m. on Thursday morning. Dr. Grey Walter, head of the Physiological Department at Burden Neuropsychiatric Institute in England, spoke on "Where Vital Things Happen" with Drs. Lawrence Kubie and Karl Pribram acting as discussants.

The final business session was held on Friday, May 1, at 9:00 a.m. At this time, the actions taken by the Council on April 30 were reported by the Secretary Pro Tempore, Dr. Kolb. These actions included the appointment of Dr. Paul E. Huston to fill the unexpired term on the Council of Dr. Addison M. Duval, the newly elected Treasurer, and the recommendation that the membership approve the Rhode Island District Branch as a District Branch of the APA. Both of these actions were approved, and the whole report was accepted by the membership upon motion from the floor. With the presentation of the gavel, Dr. William Malamud was formally installed as President of the Association for the coming year, and he announced the new Officers for the Assembly of District Branches: Dr. Alfred Auerback, Speaker; Dr. John R. Saunders, Speaker-Elect; and Dr. Lester Shapiro, Recorder. After a few brief remarks by the new President, this final session was adjourned. The 115th Annual Meeting was officially closed at 5:00 p.m. on May 1.

SUMMARY OF MEETINGS OF COUNCIL AND EXECUTIVE COMMITTEE, MAY 1958 TO MAY 1959

This report presents in summary form the principal actions of the Council and the Executive Committee at meetings held throughout the year. Many routine matters, such as referrals to Committees prior to definitive actions, are not included. Copies of the full minutes have been forwarded to the officers of each District Branch and Affiliate Society following the various meetings to keep their members informed of the matters that were considered and the action that resulted.

Executive Committee Meetings, June 28, and September 14, and October 31, 1958.

Approved the recommendations of the Committee on National Defense for Standards to be suggested to the Civil Aeronautics Administration (name changed to Federal Aviation Agency) regarding the physical and mental examination of applicants for licensure in civil aviation. Approved a sample certificate to be issued to hospitals inspected and approved by the Central Inspection Board. Approved the selection of the State of Illinois as the situs for the filing of the group insurance plan for APA members. Authorized the appointment of a committee to review the Psychiatric Research Fund and APA relations with it. Approved the continuation of the Smith, Kline and French Fellowship Committee for another 3 years. Approved a resolution presented by the Therapy Committee stating: "Whereas scopolamine, if used indiscriminately, can have deleterious effects, be it resolved that the APA recommends that compounds containing scopolamine be dispensed on medical prescription only." Requested that the President appoint a Commission to study the needs and policies representing the standards of the APA in research and treatment in psychiatry and appropriated \$7000 for interim financial arrangements for the Commission pending the November meeting of the Council. Recommended that an honorarium of \$250 be awarded annually to the Fellowship Lecturer (Academic Lecturer) beginning in 1959. Approved a plan to hold a meeting of State Mental Health Commissioners at the Mental Hos-

pital Institute at no cost to the APA. Authorized payment of bills incurred by the House Committee for renovation of the Central Office in excess of the original budget appropriation. Authorized the House Committee to proceed with the Dedication Ceremony for the Central Office in accordance with its preliminary plans. Authorized the Executive Assistant to sign grant applications submitted by the APA to the National Institute of Mental Health. Authorized the Committee on Disaster and Civil Defense to participate in a seminar on civil defense and disaster, and to seek funds from the Office of Defense and Civilian Mobilization to develop a training film in adjunct with the manuals published by the Committee. Appointed Dr. George Tarjan to the Council to fill the vacancy occasioned by the election of Dr. C. H. Hardin Branch to the office of Secretary. Reaffirmed its approval in principle of a proposed organization for Mental Hospital Personnel under APA auspices. Approved a letter of agreement with Dr. Daniel Blain covering his work with the Manpower Project. Directed that the management of APA funds be referred to the Medical Director and the Treasurer for study in consultation with the Chairman of the Budget Committee and the Executive Assistant. Approved in principle a booklet on mental health in industry prepared by the Committee on Industrial Psychiatry (subsequently renamed Committee on Occupational Psychiatry). Directed that the Committee on Certification of Mental Hospital Administrators be limited to a maximum of 7 members appointed for a 3-year term so staggered that approximately one-third will retire each year, that there should be no consultants to the Committee, and that the Chairman and Secretary be appointed on the same basis as other Committee members. Approved a schedule of regulations to govern reimbursable staff travel expenses as presented by the Executive Assistant. Directed that the Ethics Committee account should be rebudgeted so that a total of \$500 be placed at the immediate disposal of the Committee for

official expenses and authorized the Committee to submit a request for a supplemental appropriation if necessary. Authorized the appointment of 3 members of the Committee on Nomenclature and Statistics for a period of 2 years, following which the Committee will revert to its normal size of 6 members. Authorized the Ad Hoc Committee in Liaison with the Canadian Psychiatric Association to meet during the fall Committee meetings. Approved recommendations of the Ad Hoc Committee on Increasing Responsibilities of the APA governing joint meetings between APA Sections and outside organizations at the APA Annual Meeting. Expressed sincere appreciation to Dr. Hugh T. Carmichael for his statesmanship in negotiating with the Joint Commission on Accreditation of Hospitals and for his service to the cause of the hospitalized mentally ill in dealing with the problem of mental hospital accreditation. Authorized the Executive Assistant to negotiate for new quarters for the New York Office in accordance with his recommendation and to sign a 5-year lease for such space.

Council Meeting, November 21-22, 1958.

Approved the minutes for Council meeting of May 10, 11, and 15, 1958, as amended. Ratified the actions of the Executive Committee meetings of June 28, September 14, and October 31, 1958. Directed that the situation regarding the proposed Bond-Strecker-Appel Award should be clarified by the Treasurer writing to the attorney for the donor specifying the conditions under which the funds for this award can be accepted by the APA. Authorized the Medical Director to expend such funds in excess of the original budget allotment as are necessary to operate the Central Office economically during the remainder of the budget year. Accepted the proposed expenditures for salaries, the retirement fund, rent for the New York Office, printing of APA publications, and maintenance of the Central Office as recommended by the Budget Committee. Accepted the request for an additional Editorial Assistant in the Mental Hospital Service. Accepted the request for authorization of increased rent for the New York Office. Approved the recommendation that the Medical Director

drop from the payroll temporary employees involved in projects terminating during the current fiscal year. Approved a request for a part-time administrative assistant for the Assembly. Did not approve, for the present time, a proposal to establish an active library at the Central Office. Approved the request for a contingency fund of \$20,000 for the President and the Council. Authorized the Budget Committee to resume its previous practice of preparing a final budget at its fall meeting for consideration by the Council in order to avoid a second meeting of the Committee. Accepted in principle the recommendations from the Commission on Long Term Policies concerning an early publication journal. Approved the current studies of the Commission on Long Term Policies and expressed hope that all will be worked out soon and brought before the Council in the near future. Approved the request of the Nominating Committee that a statement be printed in the Journal indicating the factors considered by the Committee in preparing the annual slate of Officers and Councillors. Directed that copies of all Nominating Committee reports be compiled for the information of subsequent Nominating Committees. Authorized members of the Commission on Principles and Position on Current Issues on Psychiatry to appear before Congress giving testimony to the best of their ability and knowledge with the advice of the total Commission and the APA Officers. Expressed complete confidence in the Commission with regard to possible testimony before Congress, and indicated that the use of the original \$7000 appropriation would be left to the discretion of the Commission in financing its activities. Requested Dr. George S. Stevenson to determine how other organizations deal with the matter of recognizing outstanding services by their members and asked that he bring a recommendation to the Executive Committee which would permit the Association to accord appropriate recognition to its outstanding members within constitutional limitations. Authorized the Medical Director to explore the possibility of incorporating the cost of psychiatric treatments into the Group Health Insurance plan in New York. Requested

the President to appoint an Ad Hoc Committee to investigate all aspects of insurance for APA members and directed that this Ad Hoc Committee develop a program of action for consideration by the Council. Viewed with sympathy the need for funds by the Central Inspection Board for the reinspection of hospitals but felt that it could not assume this responsibility. Expressed a vote of confidence to the Central Inspection Board, Dr. Gerty, and Dr. Hugh T. Carmichael for the fine work they are doing in relation to the situation regarding the Joint Commission on Accreditation of Hospitals. Approved the proposed amendments to the Constitution regarding membership as suggested by the Assembly: Article III, Section 3, and new Sections 12, 13, 14, and 15 of the Constitution and Article V, new Section 3 of the By-Laws. Approved the proposed amendments in Article V of the By-Laws involving proposed new Sections 1, 2, 4, 5, 6, and 7, as suggested by the Assembly, with an addition to new Section 2 to read, "A District Branch may elect as affiliates, physicians practicing or residing in its geographical area who are not eligible for membership in the Branch. Affiliates are not members and will be ineligible to vote or hold office in the Branch." Approved the recommendation of the Policy Committee that funds be authorized for circulation to the membership via the Mail Pouch of cogent portions of a letter from the American Psychological Association regarding the latter's position on certification for psychologists, together with an appropriate introductory paragraph. Approved the application of the Santa Clara-Monterey Psychiatric Society for Affiliate Society status and directed that it be presented to the membership for final vote. Approved in principle the recommendation of the Policy Committee for publication of proceedings of Divisional Meetings at no expense to the APA, with the APA Publications Department functioning in a manner similar to that now followed with respect to the Research Reports. Approved the recommendations by the Ad Hoc Committee on Education in Public Hospitals in Liaison with the American Psychoanalytic Association that the Central Office keep

on file a list of psychoanalysts who are willing to participate in an educational program in state hospitals, that this service be publicized in the Mail Pouch, the Journal, and Mental Hospitals, and that the Central Office take charge of carrying out this service. Approved the proposed standards for training in child psychiatry as recommended by the Committee on Child Psychiatry and the Committee on Medical Education. Approved the recommendations of the Committee on History of Psychiatry regarding the development of a library in the Central Office, the assembling of archives, records, transactions, and proceedings of the Association, and requested the Medical Director to seek funds for and initiate a research project on the historical development of contemporary American psychiatry. Recommended that the Budget Committee consider appropriating \$2500 to \$3000 for the purpose of beginning a collection of historical material for the Library in the Central Office. Approved the recommendation of the Committee on Medical Education that the *Descriptive Directory of Psychiatric Training in the United States and Canada*, published in 1955, be revised and reprinted on or about October 1960, and authorized the Central Office to carry out the necessary compilation of data and organization of the Directory with editorial assistance as to format, index, and length of descriptions by the Committee on Medical Education. Approved the unanimous sentiment expressed by the Committee on Medical Education that there is no present indication for action on the proposal for adoption of a uniform date of appointment for psychiatric residents, and that the present operation of methods of appointment permits a flexibility which is useful both to the training centers and to the men applying for training. Approved a statement submitted by the Committee on Medical Education regarding the importance of the Conference of the World Medical Association to be held in Chicago in the summer of 1959. Authorized the Committee on Therapy to collect data regarding the amount and type of psychotherapy being done with chronic schizophrenics including a questionnaire to pro-

vide information as to where such psychotherapy has been done. Approved the preparation of a statement by the Committee on Therapy which would endorse the recent statement by the American Medical Association concerning current problems related to hypnosis. Directed that the Committee on Therapy continue to consider the problem of hypnosis with special reference to those matters of particular interest to psychiatrists. Authorized the Committee of Standards and Policies to seek outside funds for a second Conference on Volunteers, the program to be initiated by the APA and co-sponsored by the American Hospital Association, the National Association for Mental Health, the American Red Cross, and the Veterans Administration. Directed that the Committee on Cooperation with Leisure Time Agencies re-submit its request for a change in name with a number of possible alternative names for consideration by Council. Approved the request of the Committee on National Defense that two additional sentences be included in the recommended Standards for the Civil Aeronautics Administration (Federal Aviation Agency) governing mental and physical examination of applicants for licensure in civil aviation. Approved a plan for publishing the proceedings of the Hawaiian Divisional Meeting as proposed by Dr. Alfred Auerback. Accepted the report of the Ethics Committee with thanks, approved the actions recommended by the Committee, and authorized the Chairman to notify each individual of the decision of the Committee in his particular case. Recorded its extreme pleasure with the manner in which the Dedication of the Association's new headquarters building was carried out on October 31, 1958, stated that the arrangements were altogether appropriate to the historic occasion, and asked the Secretary to communicate these sentiments to the APA House Committee who planned the program, to the Central Office staff who executed it, and to Mrs. Henry Laughlin and her Committee of Volunteers who so generously contributed to the success of the occasion. Did not approve a request for the compilation and maintenance by the Central Office of a listing of summer

employment in psychiatry for medical students because staff is not available to undertake such an operation at this time. Approved the recommendations submitted by Dr. Daniel Blain regarding the financial arrangements for the Manpower Project with the stipulation that September 15, 1958 be continued as the beginning date for the preliminary contract. Approved in principle a Psychiatric-Psychological Evaluation Program by the United States Information Agency and referred it to the Committee on National Defense for further study. Approved in principle the proposed plan for Alan Gregg Memorial Consultancies in Psychiatry, which would make it possible to utilize fully the abilities and the experience of aging and aged psychiatrists.

Executive Committee Meetings, January 24, 1958 and March 7, 1959. Directed that the two APA members of the Psychiatric Research Fund Council, Dr. Gerty and Dr. Branch, should meet with this Council and proceed according to their best judgment on the proposed dissolution of the Fund and merger with Research In Schizophrenia Endowment. Approved in principle a plan for a Conference on a Restudy of Present Standards which would make recommendations concerning their future development, elaboration, and application. Directed that, in view of the invitation by Canada to the International Congress of Psychiatry, an invitation not be extended by the U. S. A. and that the APA firmly support the meeting in Canada. Approved the appointment of Dr. Francis Braceland, Dr. Winfred Overholser, and Dr. Lothar Kalinowsky to a committee to work out arrangements between the U. S. A. and Canada for the International Congress. Reiterated with enthusiasm its approval in principle of the proposal for the establishment of Alan Gregg Memorial Consultancies in Psychiatry. Expressed its approval of a certificate to be presented to Dr. Seymour Vestermark on March 7, 1959. Requested the President to appoint a Commission on Awards and Recognitions to present recommendations at the Fall Council meeting on proposals for types of awards, format, method of selection, and continuance of the Commission itself. Ap-

proved a restatement by the Secretary of the policy governing joint meetings between APA Sections and outside organizations at the APA Annual Meeting. Directed that the publication of the proceedings of the APA Teaching Institute at McGill University not be underwritten by operating funds of the APA. Approved the revised budget for 1959-1960 as recommended by the Treasurer with expenditures totalling \$716,749 and income estimated as \$763,125.

Approved a proposed plan for coordinating of Journal and Mail Pouch advertising on a one-year trial basis as presented by Mr. Davies with the understanding that it will produce more income for both the Journal and the Mail Pouch. Stated that the APA is not able to participate in a commercially sponsored conference such as the one held by the National Hearing Aid Industry but indicated that the Conference is free to invite members of the Association to participate as individuals. Requested the Medical Director to prepare a letter commending Mrs. Marion Hildebrand for her volunteer work for the Mental Hospital Service. Expressed gratification that the World Health Organization had designated April 7, 1959 as World Mental Health Day, thus giving international recognition to one of humanity's greatest health challenges and furnishing a fitting prelude to World Mental Health Year in 1960. Also directed that this statement be disseminated to the membership and that the Medical Director relay it to appropriate organizations and leaders. Approved the appointment of Dr. Joel Handler as APA representative to a meeting of the Joint Committee to Study Paramedical Areas in Relation to Medicine, held on April 4-5, 1959. Voted that in view of its minimal participation, the APA withdraw from the Psychiatric Research Fund and not continue in any official capacity, and authorized the President and the Secretary, Board members by virtue of their APA offices, to resign from their positions with the Psychiatric Research Fund. Reiterated its approval for the appointment of a committee to review the financial structure of APA insurance plans, with a \$1,000 appropriation for committee expenses. Voted to continue the contract with Dr. Daniel Blain for the Manpower Project

until June 5, 1959 with some modifications of the original conditions. Directed that an amount not to exceed \$2,000 be made available to the Coordinating Committee on Technical Aspects of Psychiatry during the current budget year to defray obligations already incurred and directed that a careful evaluation be made of inevitable expenses for the coming year. Asked the President to appoint a delegate to the International Congress on Mental Retardation to be held in the summer of 1959. Authorized payment of obligations incurred by the Assembly of District Branches in excess of its budget for the 1958-1959 fiscal year. Extended a vote of commendation to Dr. Mathew Ross for his work in stating principles for planning facilities and services for psychiatric care, authorized him to continue with this project together with the American Hospital Association, and to work towards publication of this set of principles in final form. Directed that the Ad Hoc Committee on Relations with the Canadian Psychiatric be dissolved and empowered the President to work with Dr. Charles Roberts on arrangements for a joint committee between the APA and the Canadian Psychiatric Association. Directed that the Medical Director proceed with a plan for obtaining donations of books for the Central Office library and for psychiatric centers abroad. Authorized APA participation in the 1960 White House Conference on Children and Youth and directed that a delegate be appointed and that \$100 be contributed to the Conference from the Council Contingency Budget.

Council Meetings, April 25, 26, and 30, 1959. The Council was informed that Dr. C. H. Hardin Branch would be unable to perform his duties as Secretary for several months because of illness. Acting under its authority as the constitutional governing body of the APA, the Council authorized itself to nominate and elect a Secretary Pro Tempore with all the powers and functions of the Secretary until such time as Dr. Branch is again able to assume the duties as Secretary. Elected Dr. Lawrence C. Kolb as Secretary Pro Tempore. Approved the actions of the Executive Committee since the Council meeting of November 21-22, 1958. Recommended acceptance

by the membership of the list of candidates for election to membership or change in status, as submitted by the Membership Committee. Voted that the APA rejoin the National Health Council and authorized the payment of dues to this organization from the Council Contingency Fund. Requested the President to appoint an Ad Hoc Committee to study the proposed addition to the By-Laws dealing with Chapters in District Branches. Directed that Dr. Howard Potter be asked to explore unofficially with the Philippine Psychiatric Association the question of whether that body might wish to make a direct request to the APA that the Philippines be included in the roster of countries served by the Association. Nominated Dr. Jack Ewalt for a term on the American Board of Psychiatry and Neurology to succeed Dr. David Boyd whose term expires December 1959. Directed that the Commission on Principles and Position on Current Issues in Psychiatry concern itself with problems that are relevant to the American Psychiatric Association as a whole and that local problems should be referred to local and District Branch Societies unless the Commission is requested specifically to assist. Requested that Dr. Francis Braceland, Chairman of the Commission, appear before the Assembly of District Branches to explain the above action. Authorized the appropriation of approximately \$12,000 per year to employ a legislative aide to work in conjunction with the Commission on Principles and Position on Current Issues in Psychiatry. Approved the continuation of the Commission for another year and accepted its report. Directed, on recommendation of the House Committee, that no portraits be hung in the Modern Founders' Room in the Central Office at the present time. Approved a plan to hang portraits of the 13 founders in the Century Club Room and directed that such portraits should be from 20-24" wide and 24-30" high, rectangular or oval, that the frames should be gilded and not wider than 4", that the portraits need not be uniform in size, style, or medium, and that original portraits are preferred if such are available. Directed that a portrait of Dr. Benjamin Rush, 36" high and 30" wide, should be

hung in the main foyer of the Central Office behind the receptionist's desk. Directed that photographs of Past-Presidents of the APA should be solicited from the individual concerned or from his family, that such photographs should be approximately 8 inches wide and 10 inches high, with a dull mat finish. These should be presented unmounted and unframed, and autographed. In case the Past-President is deceased, a facsimile of his signature will be reproduced on the photograph from an available copy. Directed the Secretary to write to all Past-Presidents and instructed the Committee on History of Psychiatry to undertake such research as is necessary to obtain a complete set of photographs. These photographs will be hung in the Presidents' Room and/or at such suitable locations as the House Committee may select. Rescinded the Standards for Electroshock Treatment of May 1953. Approved APA membership in the World Federation for Mental Health and authorized payment of membership dues amounting to \$92.80. Received a report from Dr. George S. Stevenson on methods of honoring outstanding work by members of the Association. On suggestion by Dr. Blain, requested the President to appoint an Ad Hoc Committee to oversee the handling of funds remaining in the Manpower Project. Approved the recommendation that the Vice-Presidents of the Association be assigned the duty of speaking before the constituent psychiatric organizations of the APA to interpret the policies and actions of the Association and to report the questions and reactions which they so gather to the Executive Committee. Requested the President to appoint an Ad Hoc Committee to review the matter of expenses and speaking engagements of Vice-Presidents. Upon recommendation of the Ad Hoc Committee appointed to study the matter of District Branch Chapters, approved in principle a plan leading to only one District Branch in each State, Province, or Territory, and stated that if it seems desirable, a Branch could organize within its geographical area one or more sub-sections known as Chapters. Referred this proposal to the Assembly for development and expressed the opinion that, in the meantime, new District Branch-

es should not be organized to cover less than a State, Province, or Territory, and that further fragmentation of present District Branches should be discouraged. Recommended that the Ad Hoc Committee to study this matter be continued as long as necessary and directed that it work in cooperation with the similar committee of the Assembly. Approved the signing of checks and the management of APA financial affairs by Dr. Addison M. Duval, the new Treasurer, effective May 1, 1959. Authorized Mr. Austin Davis, Executive Assistant, to continue to sign checks on all checking accounts of the Association, subject to present voucher controls or by any different system of voucher controls adopted by the Treasurer on recommendation of the Auditor. Authorized Mr. Joseph Turgeon to continue to sign checks on the checking account in the Riggs National Bank in Washington, D. C. Authorized the Medical Director and/or the Committee on Grants and Awards to receive spontaneous funds for establishment of a Seymour D. Vestermark Memorial Lecture on the subject of Psychiatric Education. Designated Dr. George S. Stevenson as APA representative to the Second National Conference on World Health in Washington, D. C. on May 7-9, 1959. Elected Dr. William Malamud as Moderator for the Council and Executive Committee for the coming year. Elected Dr. Francis Gerty and Dr. Jacques Gottlieb to serve on the Executive Committee during the coming year. Elected Dr. Paul Huston to the Council to fill the unexpired term of Dr. Addison M. Duval, the newly elected Treasurer. Approved the appointment of Dr. Arthur Unger and Dr. Lloyd Morrow to the Membership Committee. Regarded favorably the work of the Committee on Relations with Psychology and encouraged it to pursue several solutions which the Committee had suggested to resolve the problems existing in this area. Expressed its realization to colleagues in the Canadian Psychiatric Association of their obligation and prerogatives to make the final decision regarding the date of the International Congress of Psychiatry in Montreal in 1961 but expressed the sincere hope that an amicable arrangement can be reached whereby this

meeting date will not conflict with that of the World Federation for Mental Health in Paris in August-September, 1961. Directed that the type "D" student fellowships given by the Smith, Kline and French Foundation Fellowship Committee be called "Vestermark Fellowships" as recommended by that Committee. Directed that it be made a rule of the Executive Committee and the Council, to be reconsidered each year, that the Medical Director be present at all Executive Sessions of either body unless specifically directed otherwise. Recommended approval by the membership of the proposed Rhode Island District Branch. Directed that an explanatory paragraph be prepared by the Committee on Constitution and By-Laws in cooperation with the Speaker of the Assembly to accompany the alternate choices for proposed amendment to Article V, Section 2 of the By-Laws. Requested the President of the Association to send a telegram to the North Dakota State Medical Association stating the APA's position regarding the appointment of a non-medical superintendent to a mental hospital and advising that, in the best interests in the care and treatment of such patients, including the mentally retarded, an adequately trained psychiatrist should serve as the principal administrator. Authorized the appropriation of \$150.00 to the Committee on Aging to conduct a re-survey of psychiatric interest and activity in the problems of the aged, utilizing a random sample of 600 members of the APA, to determine any change in attitude or practice since the first survey carried out three years ago. Expressed appreciation for the fine job done by Dr. Frank Curran in his position as Chairman of the Coordinating Committee on Technical Aspects of Psychiatry. Authorized the appropriation of an additional \$1000 to the Coordinating Committee on Technical aspects of Psychiatry for the 1959-1960 budget year. Continued the Ad Hoc Committee on Education in Public Hospitals in Liaison with the American Psychoanalytic Association. Changed the Ad Hoc Committee on Increasing Responsibilities of the APA to a Standing Committee on Internal Activities of the APA, with rotating membership, reporting directly to Council. Continued the Ad Hoc

Committee on an Organization for Mental Hospital Personnel for another year. Authorized a change in name for the Committee on Legal Aspects of Psychiatry to the Committee on Psychiatry and the Law. Authorized a change of name for the Committee on Industrial Psychiatry to the Committee on Occupational Psychiatry. Continued the Ad Hoc Committee on District Branch Committees for another year. Authorized the annual appointment of an official liaison representative to the American Bar Association as recommended by the Committee on Psychiatry and the Law. Approved a recommendation for a change in size of the Committee in Liaison with the American Hospital Association to permit six representatives from each organization on the Committee. Approved the recommendation of the Ad Hoc Committee on an Organization for Mental Hospital Personnel that District Branches be encouraged to hold local Mental Hospital

Institutes on a trial basis to see if the relations with non-psychiatric hospital personnel under study by this Committee could be thereby established. Authorized the Committee on National Defense to send a letter to the Federal Aviation Agency reaffirming its previous suggestions regarding mental and physical examinations of prospective civilian pilots. Upon recommendation by the Committee on National Defense, voted to record through the Medical Director its regret and objection concerning the extreme limitation of psychiatric treatment in the Medicare Program. Authorized the Medical Director to assist in the establishment of a proposed organization of non-medical mental hospital business managers. Directed that no member of the Council, nor any candidate for this office, should be scheduled on the Annual Meeting program on Thursday.

LAWRENCE C. KOLB, M.D.,

Secretary Pro Tempore

TREASURER'S REPORT : AMERICAN PSYCHIATRIC ASSOCIATION

At the close of our Fiscal Year, which ended March 31, 1959, we find we have been able to live through our most difficult period, financially, without borrowing any money, with a home which is debt free and with assets totalling over $\frac{1}{2}$ million dollars.

On that date our position was as follows :

Cash on hand (including savings accts.)	\$ 53,111.32
Accounts receivable	14,109.15
Marketable securities (book value \$88,134.60)	152,600.00
Central office land and building at cost	\$275,907.30
Furniture and equipment (Central Office)	15,229.94
	<hr/>
	291,137.24
Total Assets	\$510,957.71

\$92,430.30 of these assets have been allocated to special purpose and restricted funds, and are therefore not available for other expenditures leaving a balance of \$418,527.41. In addition, there is a total of \$47,134.76 in cash and securities in Restricted Funds.

Against these assets are liabilities of one type or another of \$85,441.62. Also the assets figure contains a paper profit of \$64,465.34 on our securities. This figure, of course, fluctuates depending on the market. Our portfolio

is sufficiently diversified, however, that, barring a general downward trend in the market, our investments represent a sizeable profit. Also it will be noted that the home and furnishings are carried in this report at cost. This is an extremely conservative figure.

If, then, we deduct our liabilities from our

assets, other than those contained in restricted funds, we still have net assets of \$333,085.79. The bulk of this consists of our home and our investments.

It may well be asked why our annual budget is so tight if we have assets of this magnitude. It should be remembered that these assets as listed here consist of debt-free property and securities at market value on March 31, 1959. The securities earned the Association \$5,864.79 last year. To liquidate

any portion of them will not only reduce our favorable financial position, but will also reduce the income to the Association. To realize cash on our property would either increase our fixed obligations by the amount of interest charged on the loan or it would permanently reduce our financial base by sale of the property. Therefore eating into these funds should be reserved for dire emergencies or as a part of a general program of liquidation.

On the other hand, it appears as though we must budget increased amounts for our fixed expenses in the future over what we have in the past. Costs continue to rise which means that it will cost us more money to do the same things we are doing now. This applies to salaries, utilities, taxes, travel, printing, postage, rent and other items. Fortunately, due

to the dedication and skill of our Executive Assistant, Mr. Austin Davies, we have been able to get by during the past year. I can assure you this has required real financial acrobatics.

The membership may find that for the next few years many projects which are desirable and worthwhile may of necessity be deferred until they can be financed within our annual income.

We have come through our most difficult year although the next two or three will also be strenuous, but we are coming out of the woods and, I confidently feel that our greatest and most productive days are still ahead of us.

R. H. Felix, M.D.,
Treasurer

NEWS AND NOTES

MILWAUKEE NEURO-PSYCHIATRIC SOCIETY.

—The annual meeting of the Milwaukee Neuro-psychiatric Society was held on Wednesday, May 20, 1959. Officers selected for the year 1959-60 are as follows: president, C. J. Buscaglia, M.D.; vice-president, George J. Martin, M.D.; secretary-treasurer, Henry Veit, M.D.; councillors remaining: Edward Carl Schmidt, M.D., and David Cleveland, M.D.

ASSOCIATION FOR THE ADVANCEMENT OF PSYCHOANALYSIS, INC.—On Wednesday, September 30, 1959, the Association will sponsor its regular meeting at the New York Academy of Medicine at 8:30 p.m. Dr. Harold Kelman will present a paper entitled "Separateness and Togetherness." The discussants will be Drs. Jack L. Rubins and Abe Pinky.

AMERICAN ACADEMY OF PSYCHOTHERAPISTS.—The fourth annual conference of the American Academy of Psychotherapists will be held October 17-18, 1959, at the Barbizon Plaza Hotel, N. Y. C. The topic is "Divergencies and Agreements in Methodologies of Psychotherapists." Dr. Robert A. Harper will present the theoreticians' viewpoint concerning the 5 schools of psychotherapy which will include the following: Rudolf Dreikurs, M.D. (Adlerian); Jule Nydes (Freudian); Laura Perls, Ph.D. (Gestalt); Carl Rogers, Ph.D. (Client-Centered); and Carl Whitaker, M.D. (Experiential). The dinner speaker will be Leonard Feldstein, M.D., Ph.D. For further information write to: American Academy of Psychotherapists, 30 Fifth Ave., New York 11, N. Y.

SOCIAL LEGISLATION INFORMATION SERVICE, INC.—This nonprofit association established in 1944, supported by contributions and subscriptions, reports impartially on

Federal social legislation and the activities of Federal agencies affecting family life, children, and community services in the areas of health, education, welfare, housing, employment and recreation. The Service takes no position for or against the legislation reported.

Subscriptions to the Bulletin may be obtained from Social Legislation Information Service, 1346 Connecticut Ave., N. W. Washington 6, D. C. Price: \$18.00 per year; single copies 25c.

CLINICAL NURSING OFFICER AT SASKATCHEWAN HOSPITAL, WEYBURN, SASK.—At the second annual meeting of the Saskatchewan Psychiatric Nurses Association held at Valley Centre, Fort Qu'Appelle, June 2-3, 1959, attention was called to the fact that the Organization of the Nursing Service at the Saskatchewan Hospital, Weyburn, was the only one of its kind on the North American Continent. The difference between this organization and other nursing services is the addition of the "Clinical Nursing Officer" whose responsibility is as an advisor and coordinator between nurse, psychiatrist and other departments. This Officer acts in a position of sapiential authority as opposed to the structural authority common to most hospitals and enables nurses to express their ideas on patient care as well as saving the psychiatrist time.

DR. TOMPKINS HEADS RELIGION AND MENTAL HEALTH GROUP.—Dr. Harvey J. Tompkins, director of psychiatry at St. Vincent's Hospital, N. Y. City, has been elected president of the Academy of Religion and Mental Health, succeeding Dr. Kenneth E. Appel, the first incumbent. The term of office is two years.

MENTAL HEALTH PROBLEMS OF AGING AND THE AGED.—The sixth report of the Expert

Committee on Mental Health titled, "Mental Health Problems of Aging and the Aged" (Technical Report Series No. 171) is currently available from the World Health Organization, Palais Des Nations, Geneva, Switzerland. Price: 60c.

PUBLIC HEALTH NEWS (NEW JERSEY DEPT. OF HEALTH).—The June 1959 issue of this publication is devoted to the psychiatric problems of childhood which are covered by 8 contributions (Drs. Senn, Kanner, Gallacher, Rose, Robinson, Brancale, V. Terrell Davis, and Carl E. Wendel).

This symposium offers a valuable survey of the more common psychiatric problems and developments of childhood and adolescence.

VOLUNTEER SERVICES TO PSYCHIATRIC PATIENTS.—A report of the Conference on Volunteer Services to Psychiatric Patients held in Chicago, Ill., June 12-17, 1958, is embodied in a 124-page book published by the American Psychiatric Association, entitled *The Volunteer and the Psychiatric Patient*.

The 5 chapters contain a description of the types of volunteer services both in and outside of the hospital and further principles for volunteer programs. There is also a bibliography of the literature on volunteers in psychiatric institutions.

The book may be obtained from The American Psychiatric Association, 1700 18th St., N. W., Washington, D. C.

DR. EDWARD E. MAYER.—The death of Dr. Mayer, prominent psychiatrist of Pittsburgh and supervising director of the Allegheny County Behavior Clinic, occurred June 2, 1959. He was 82 years of age.

He was a graduate of the University of Pittsburgh in both arts and medicine and had been associated with city and county mental health agencies for almost 60 years. He was a frequent contributor to medical

literature and had edited Oppenheim's *Diseases of the Nervous System*.

Dr. Mayer was active as consultant both in private practice and in criminal cases. A sentence of his is worth quoting and giving serious consideration: "It is wrong to think of antisocial behavior as always due to mental illness, and that all delinquents need psychiatric care."

He had served as Medical Director of Fairview Sanitarium and as Associate professor of Psychiatry, University of Pittsburgh; also as neurologist and psychiatrist to the Presbyterian Hospital and the Woman's Hospital of Pittsburgh, and as psychiatrist to the juvenile court of Allegheny County.

In Dr. Mayer's death Pittsburgh has lost one of her most distinguished and respected citizens and physicians.

AMERICAN PSYCHOSOMATIC SOCIETY.—The Society will hold its 17th annual meeting at the Sheraton-Mt. Royal Hotel in Montreal, Canada, on Saturday and Sunday, March 26-27, 1960.

The Program Committee would like to receive titles and abstracts of papers for consideration for the program no later than December 1, 1959. The time allotted for presentation of each paper will be 10 or 20 minutes.

Abstracts, of 2 or 3 pages, in 9 copies, should be submitted to Eric D. Wittkower, M.D., Chairman, Program Committee, 265 Nassau Road, Roosevelt, N. Y.

AMERICAN NEUROLOGICAL ASSOCIATION.—At the 84th annual meeting of the American Neurological Association held in Atlantic City, N. J., June 15-17, 1959, the following officers were elected for the year 1959-60:

President: Derek Denny-Brown; president-elect: Harold G. Wolff; 1st vice-president: Charles Rupp; 2nd vice-president: Samuel Brock; secretary-treasurer: Melvin D. Yahr; editor of the transactions: Melvin D. Yahr; assistant secretary: Charles H. Millikan.

Dr. Bernard J. Alpers was elected to the Council for 5 years, Dr. Benjamin Boshes

for 2 years, and Dr. Adolph L. Sahs was appointed as a Representative to the American Board of Psychiatry and Neurology.

The following were elected to Active Membership in The American Neurological Association: David B. Clark; Robert Fishman; Eli S. Goldenson; Howard Krieger; William M. Landau; Tiffany Lawyer; Lewis L. Levy; Leo Madow; Kenneth R. Magee; John S. Meter; Lewis P. Rowland and H. Edward Yaskin.

Elected to Associate Membership were: William S. Battersby and Irving H. Wagman.

Elected to Corresponding Membership: Abraham Mosovich.

The 85th annual meeting will be held June 13-15, 1960, at the Statler Hotel in Boston, Mass.

THE FOUNDATIONS' FUND FOR RESEARCH IN PSYCHIATRY.—October 15, 1959, is the next deadline for receipt of applications for research fellowships in psychiatry, psychology, sociology, neurophysiology, and other sciences relevant to mental health. The following deadline is January 15, 1960.

Applicants for fellowships should have completed their residency training and preferably have had several additional years experience in research. Interdisciplinary research training is encouraged as is additional training in the applicant's own field.

The Foundations' Fund also makes grants in support of research in mental health. Completed applications for research grants in-aid should be filed not later than December 10, 1959.

For further information write to Foundations' Fund for Research in Psychiatry, 251 Edwards St., New Haven 11, Conn.

AMERICAN ELECTROENCEPHALOGRAPHIC SOCIETY.—The newly elected officers of the American Electroencephalographic Society, elected at the June 1959 meeting in Atlantic City, are as follows:

President: Dr. Arthur A. Ward, Jr., Seattle 5, Wash.; president-elect: Dr. Jerome K. Merlis, Baltimore, Md.; secretary: Dr. George A. Ulett, St. Louis, Mo.; treasurer: Dr. Isadore S. Ziff, Richmond, Va.

WORLD POPULATION AND POTENTIAL FOOD SUPPLY

From the facts presented, it is obvious that the present accelerated upsurge of population in the world cannot be disregarded without disaster. The trends predicted by Malthus are apparent today. The world population has more than quadrupled since 1650, but the average yield of food crops per unit area of land generally have been increased at a much lower rate . . . Some measure of population control is necessary. Mankind ultimately must live within his resources or suffer the consequences of the controls imposed by nature.

—WARREN H. LEONARD,
Professor of Agronomy,
Colorado State University.

BOOK REVIEWS

THE CHEMICAL CONCEPTS OF PSYCHOSIS.

Edited by Max Rinkel and Herman C. B. Denber. (New York: McDowell, Obolensky, Inc., 1958, pp. 485, \$7.50.)

This book contains up to date reviews by 54 leaders in the various aspects of this field, and is, therefore, strongly advised for all individuals seeking an understanding of the present frontiers in research in this rapidly advancing area of experimental psychiatry. It begins with Henry Osmond's historical contribution in which Lewin's book, *Phantastica*, a pioneer in psychopharmacology, is noted. Among the path-finding work he considers that of Macht, who was the first to report the possibility of a substance in the serum of schizophrenics different from any found in nonschizophrenic normal individuals. He also quotes the investigations of Hoffer, Baruk, Buscaino, Hofmann, Heath, Hoch, Woolley, Rinkel and Mayer-Gross, and it is significant that each of these leaders reviews his own contributions in the same volume. Winter and Flataker, Streiffer and Kornblueth follow the lead originally suggested by Macht and find evidence for chemical differences between the sera of normal controls and schizophrenic patients. The list of papers includes Denber's report concerned chiefly with mescaline-induced changes in human subjects, and Evarts' electro-physiologic and behavioral studies of psychotomimetic drugs. Cerletti emphasizes the very small fraction of LSD that enters the brain and Brodie evaluates the role of serotonin as a chemical transmitter. Other experimental work was done on humans by Sherwood, on animals by Feldberg and Marrazzi, and on brain tissue by Bogoch. In all these instances suggestive conclusions are drawn on possible chemical deviations in schizophrenia. The Austrian psychiatrists, Hoff and Arnold, present an amazing analysis of the unsettled problem of schizophrenia and the thoughts of Brill, the Sacklers, Kline, Reiss and Letemendia are all of value to anyone concerned with progress in the organic approach to psychiatry. Block presents a striking suggestion that schizophrenics are victims of chronic poisoning. In contrast to normal individuals in whom the incorporation of amines into proteins is prevented, such an incorporation takes place in schizophrenic patients who are, therefore, subjected to the toxic effects of amino proteins.

The last article is that of Gilbert Cant, who

presents a nontechnical review of the volume's contents and explains to the reader not versed in biochemistry the meaning of the new results. It is hoped that enough has been said in this brief review to convince the potential reader that he can acquire a more than passing facility with this many-faceted biochemical attack in psychiatry by perusing these important papers and reviews in this carefully edited volume prepared in an attractive and readable format.

Galesburg, Ill.

COMMUNICATION, ORGANIZATION, AND SCIENCE. By Jerome Rothstein. (Indian Hills, Col.: Falcon's Wing Press, 1958. pp. 110. \$3.50.)

The steadily increasing implications of information theory for the biological sciences (as evidenced in the fields of genetics, immunochemistry, and neurophysiology), make the appearance of a book such as this a timely event. Although written by a physicist (and carrying a long and scholarly foreword by a fellow physicist) the range of this book is of the widest. It starts with a consideration of the relation of the process of information to entropy, and goes on, by way of chapters on Measurement and Communication and their relation to Thermodynamics, to a discussion of the essential elements of language, and the processes partaking in the construction of scientific theory. The last chapters are devoted to an application of the "Organization Concept," as developed by the author, to the Theory of Games, and the behavior of organized mechanisms in random game situations. It ends with a tantalizingly brief statement of minimal desiderata needed for the construction of the universal medium of communication (i.e. a universal scientific language), and with a forceful Credo looking towards a "Unified World Outlook."

In the welter of ideas propounded by the author with clarity and elegance, the non-mathematical psychiatric reader can but select a few items which point to his own subject. One is the argument, advanced in the foreword by Dr. Muses, and extended subsequently by the author, for a need for the conceptualization of the topology, i.e. struc-

ture, of Time. This intra- and inter-connectivity of time points and time intervals Dr. Muses names 'Chronotopology.' "The appreciation of time intervals are merely the measure of time ; they are no more time than rulers are what they measure. Of the nature and structure of time itself investigators have all but been silent." One would fully endorse this view, and note the strange way in which this, as yet undeveloped, area provides a meeting ground between the physicist and the sensory physiologist. For both are becoming increasingly cognizant of the way in which a structuring of events in time (in terms of probability) defines these very events, and makes possible their manipulation. In neuropsychology, as in physics, the time dimension is replacing the older dimension of space, an evolution not unlike that undergone by physics towards the turn of the present century.

The ideas proposed by Dr. Rothstein lead on naturally from the ideas outlined in the foreword. Starting with Boltzmann's discovery of the statistical explanation for thermodynamical entropy, he examines entropy as a measure of information by the selection of a message. "Selection of a subensemble from a given ensemble generates an amount of information equal to the difference of the entropies of the two ensembles." This "Set" and "Subset" view he applies successively to the concepts inherent in logic, and the evolution and structure of language as a means of obtaining, and communicating, meaning. The argument is fluid and alive, and ultimately leads to a discussion of organization of data by machine, including the "Well Informed Heat Engines" developed in living matter at macromolecular level. Pervading the argument is the concept of the isomorphs ; the best information-machine we are making, and are likely to make, is built on specifications not unlike the strange molecular machines which make up the very stuff of life.

Whether the coding and memory machines which Dr. Rothstein envisages for the future will indeed expand or contract our lives or the lives of our successors, the message of this essay is clear and relevant. The mathematical and engineering techniques hitherto only inadequately applied to biology may hold profound implications for neuropsychology, psychology and psychiatry. Their core is the structuring and relatedness of events to time, and the provision of adequate techniques for their

apprehension and their analysis. Whether we like it or not, the tide of a major scientific evolution is flowing through the Behavioral Sciences ; Dr. Rothstein does them a service by charting their currents in his clear and incisive way.

ADDISON M. DUVAL, M.D.,
Saint Elizabeths Hospital,
Washington, D. C.

LA SCHIZOPHRENIE. By Guy Delpierre. (Geneva : Chas. Fomara, 1957, pp. 109.)

This small monograph consisting of 7 chapters is from the International Institute of Psychology and Psychotherapy. Several definitions of the term "schizophrenia" are given including those of Bleuler, Deny, Levy-Valensi, Kretschmer and Claude, the psychogenic and neurogenic factors of etiology are emphasized and the symptoms are enumerated and classified.

In the chapter on dissociation the author points out the differences between this reversible phenomenon and "dementia" and describes the "vital difficulties" the patient has with eternal reality, with the body image (the "mirror sign" is given a special consideration), and with the affective, intellectual and interpersonal components of dissociation.

Three of the Kraepelinian types of clinical constellations are presented, namely, hebephrenic, catatonic and paranoid with their differentiating characteristics. A chapter on the development of the disorder is given with the differential diagnosis from known brain diseases and psychoneuroses and one on pathological anatomy with the comments limited to the histopathology and disturbed neuropsychology of the brain structures.

The 9 pages devoted to therapy considers very briefly the methods of Federn, Fromm-Reichmann, Melanie Klein, Rosen and Secheyhaye.

Since there is no author's preface or foreword, the reasons for writing are not quite clear ; however as a condensed text it may be useful to teachers of psychiatry who wish to make a brief review of the phenomenologic aspects in preparing class material. The bibliography (45 items) refers very largely to French sources, but a considerable number of other authorities are quoted without references.

Princeton, N. J.

IN MEMORIAM

KONSTANTIN MIHAILOVICH BYKOV

My first memory of Bykov is that of meeting him in Pavlov's laboratory in the Institute of Experimental Medicine, Petrograd, 1922, and my last when I bade him goodbye as he was leaving the United States in June 1958. After Pavlov, he has done perhaps more to advance the experimental science of the conditional reflex than has any other of Pavlov's pupils. His death in May 1959 in his early 70's removes the best known of the pupils of Pavlov.

Like Lomonosov and many other Russian scientists, Bykov was of humble origin, and like Pavlov he was educated for the priesthood. After studying medicine, he worked with two distinguished Russian physiologists, Pavlov and Uktomsky, the neurophysiologist. Most of his life was devoted to a steady and unremitting expansion of the investigation of the conditional reflex concepts, by thorough, well designed, and laborious experimentation on the interrelation of the viscera and their adaptation to the external and the internal environment through the mechanism of the conditional reflexes. This work was summarized in *The Cerebral Cortex and the Internal Organs* (New York, 1957, tr. by Gantt). For several decades he worked tenaciously and patiently as a pioneer and almost alone in this field, assisted and encouraged by his wife. However with the gradual increase of funds accorded scientists by the Soviet government, he expanded his physiological department at the Academy of Sciences, Leningrad, which with its branch at the subsidiary genetic laboratory in Koltushi, became the second largest research institute in the Soviet Union, having on its staff a total of 700, 200 of whom were scientists. He studied practically all the important viscera in connection with their acquisition of conditional reflexes and their inter-relations, viz. the interoceptive conditional reflexes.

Bykov became the spokesman for Pavlovian physiology after Pavlov's death. This was done through a firm belief in the soundness of the teaching of his master.

Although he stood at the pinnacle of his profession in Russia, he was never extravagant in his own claims, and accorded the most credit for his concepts to Pavlov. He was not a member of the Communist Party and to the best of my knowledge he kept his science free from subservience to politics. Outspoken in his criticism and opinion, he was nevertheless conservative.

A year before his death, he visited the U. S. A. for the first time, at the invitation of the American Psychiatric Association and of the International Gastroenterological Society, speaking before these bodies in San Francisco and in Washington, lecturing en route to the students of Dr. Magoun, in Los Angeles, at Little Rock and at the Johns Hopkins University.

Bykov's sojourn of 5 weeks in the U. S. A. had the double effect of changing his point of view about our country and our opinion of the Russian scientists. He said that when he came here, owing to the articles of Ehrenburg, he expected to be stoned, and that he was amazed to find conditions so different from what he had imagined. His simplicity, humor and genuine courtesy spread an aura of charm everywhere he went. He was described as an "honest and upright gentleman, distinguished and dignified looking, and in his behavior he was the antithesis of what we have been led to expect from Soviet Russia" (John E. Peters). The American Psychiatric Association honored him by proposing him as an honorary member, the first from the USSR. His wife was killed in an automobile accident two years ago. He is survived by a devoted daughter, Tamara, a musician in the Leningrad Theater. His friendly and sparkling humor shining through a dignified mask impressed all those who met him here, and converted even the most obdurate to feel the force of the potential friendship of the scientists of his country and ours.

Johns Hopkins School of Medicine.

DURHAM PLUS FIVE YEARS: DEVELOPMENT OF THE LAW OF CRIMINAL RESPONSIBILITY IN THE DISTRICT OF COLUMBIA

ANDREW S. WATSON, M.D.²

Five years have passed since the U. S. Court of Appeals for the District of Columbia handed down its precedent-breaking opinion in *Durham v. United States*(1). This case, establishing a new test for criminal responsibility in the District of Columbia, occasioned wide comment in the medical and legal literature. It was hailed as a great forward step in bringing the law of responsibility closer to the concepts of modern dynamic psychiatry. Many prominent lawyers and a few psychiatrists regarded it with anxiety saying that it would confuse juries and raise serious legal problems because of its "vagueness." Five years and many appellant opinions later, it is possible to review these fears in the light of subsequent experience.

Most of the multitude of papers written about *Durham*, center around several key issues(2). Psychiatrists generally laud this opinion because it will "expand the area of inquiry and communication of the medical expert as a witness"(3) as well as help him to communicate his findings in his own language rather than in the cramped and distorting expressions of legal terminology(4). Opinions may be delivered in the context of clinical examination and observation—not as inquisitorial pronouncements regarding moral guilt. The determination of guilt will be left where it belongs, in the laps of the triers of fact be they judge or jury.

Legal papers focus their challenge of *Durham* mainly around the issues that its definition is too vague and ambiguous, and it will tend to befuddle and confuse the jury in its efforts to establish responsibility(5). Lawyers are reluctant to give up the clear and precise language of *M'Naghten*(6, 7). If in fact *M'Naghten* is clear and

precise, whether or not it conforms to any scientific psychology, is a moot point. Many express the fear that this law will so broaden the definition of insanity that many criminals will be turned loose to carry on further their anti-social behavior. This fear disregards the fact that in all jurisdictions, commitment of some sort automatically follows a finding of not guilty by reason of insanity. It is a separate question legally and must not be confused with the determination of responsibility(8).

When these papers were written, they were academic discussions and speculations of what *might* happen. Now, 5 years later, we can evaluate at least partially, the accuracy of these expectations and fears. I have had the opportunity to study the trial records as well as the appellate opinions of most of this line of cases, and it appears to me that in general, the Court of Appeals has progressively spelled out and clarified the issues arising from this new test. Many of the problems created by *Durham* have been met and solutions put forward.

Many legal scholars have shown reluctance to adopt such a liberalized rule stating that it is too far advanced for the current status of psychiatric knowledge, and that also it will permit the psychiatric expert to pre-empt the determination of responsibility. This they give as grounds for clinging to the long obsolescent rules of *M'Naghten's Case*(9). I would like to make several general observations about these cases before touching upon them separately.

The most striking feature of the post-*Durham* insanity cases is the failure by nearly all the psychiatric experts to utilize the new rule for its intended purpose. *Durham* asks the psychiatrist: (1) whether the defendant has a "mental illness"; (2) whether the alleged criminal act is the "product of the mental illness"; and (3) it asks him to explain, in the language of

¹ Read at the 115th annual meeting of The American Psychiatric Association, Philadelphia, Pa., Apr. 27-May 1, 1959.

² The Law School, University of Michigan, Ann Arbor, Mich.

his own specialty, the way in which the mental illness caused the defendant to commit the alleged crime. *Durham* explicitly states that this test is defined in general terms so that the expert will be free to testify without being limited by, or forced to use, language and definitions which are foreign to the current theories of his specialty (10). Until early 1958, the cases following *Durham* singularly failed to provide this sort of testimony. The testimony of most of the psychiatric experts continued to list classical symptoms of psychiatric syndromes, without discussing them from the standpoint of how they motivated or were related to the alleged criminal act. The records are replete with such words as "insanity," "psychosis," "schizophrenia," and "irresistible impulse," the peculiar clichéd idiom of this kind of case for more than 100 years (11). We find prosecution, and defense counsel frequently utilizing psychiatric language they obviously do not comprehend. Likewise, psychiatrists glibly use expressions like "incompetent," "unsound mind," and "insane"; legal words with no psychiatric or medical meaning (12). In short, discussion between psychiatrists and lawyers remained at the pre-*Durham* level, where stereotyped language, long since isolated from the roots of its legal or medical meaningfulness, continued as the principle vehicle for communication. Little if anything comprehensible or useful was conveyed to jury or judge in this manner, and their fact-finding about sanity, surely was due to impulse and chance, as often as it was to reason.

This continuing failure to communicate has been the subject of much discussion in appellate opinions since *Durham*. In fact, these subsequent opinions regarding problems of psychiatric expert testimony are so well written that abstracts from them would make an excellent manual for psychiatric court-room practice. Before making further general observations, let me review now the psychiatrically significant features found in the post-*Durham* cases.

I have already commented upon the much discussed case of *Durham*, and so will pass to the next case of importance, *Stewart v. U. S.* (214 F.2d 879). This case tried before *Durham* but appealed after

it, still came under the right-wrong test for criminal responsibility. However, the Court of Appeals held that when the trial judge charged the jury, "... the court's attempted distinction between 'mental disease' and 'mental disorder' was at least confusing" (ibid at 881). It went on to say that "Probably this attempted distinction was meant to implement the court's view that psychopathy is not a 'mental disease' and cannot relieve one from criminal responsibility" (ibid, 882). The opinion then notes that even under the old test for responsibility, the determination of what kind of mental illness might result in a finding of "not responsible," was a matter for the fact-finders (jury or judge, if no jury) and the judge's charge therefore contained "fatally damaging error." The Court observed that this case would be re-tried under *Durham*, and made it quite clear that it anticipated the inclusion of evidence of all forms of psychopathy under its new rule. If the meaning of this opinion had been well understood, it might have obviated some of the confusion which followed about the status of sociopaths under *Durham* (13). It should be emphasized that the policy decision of what the standard for responsibility will be, is a social decision expressed through the law—not a matter which psychiatrists can settle on or off the witness stand. As private citizens we may have our own opinions, but they must not get mixed up with our courtroom testimony (14).

Taylor v. U. S. (222 F.2d 398) (handed down in March, 1955) is important for its definition and discussion of the pre-trial psychiatric handling and examination of defendants likely to raise the insanity defense. Taylor had been committed following judicial determination of incompetency to stand trial, and when he regained his competency and was tried, the government introduced testimony (over defense objection) by the doctors who treated Taylor in St. Elizabeths. Defense argued on appeal that this was breach of the privileged communication District of Columbia patients have by statute (D. C. Code [1951] § 14-308, 29 Stat. 138).

The Court of Appeals, in its opinion, stated that this testimony was inadmissible

because of the privilege, and furthermore, it was inadmissible because of the extended protection given to information uncovered during competency hearings. We psychiatrists should pay special attention to this latter point because of the frequency with which we introduce information into our competency reports which not only is irrelevant to the question of competency, but greatly jeopardizes defendant's rights in his subsequent trial. This is an ethical as well as a legal question, which deserves closer scrutiny.

The second appeal of Monte Durham is worth a brief comment. In March of 1956, the Court of Appeals reversed Durham's second conviction (237 F.2d 760), after the trial court made essentially the same error it had in the first trial. The reluctance of some of the trial courts to accept the new rule, became quite apparent at this time. We shall see further evidence of this in later cases.

The next important case is that of *Douglas v. U. S.* (239 F.2d 52 [1956]). In this opinion the court takes up two problems of interest to us: 1. The question of the burden of proof in an insanity case, and 2. The relative weight of psychiatric versus lay testimony in these matters. In all criminal prosecutions there is a presumption of sanity in the defendant. Since the Supreme Court's opinion in *Davis v. U. S.* (160 U. S. 469 [1895]), once "some evidence of insanity" has been introduced by defense, the burden of proof shifts, and prosecution must then prove sanity "beyond a reasonable doubt." Though *Davis* was decided in 1895, little clarification of this issue has occurred since then. The *Douglas* case leaves the variable degrees of proof to be defined later, but it goes so far as to make the unusual statement that

In an appropriate case there is a duty to set aside the verdict of guilty and to direct a verdict of not guilty by reason of insanity—a duty to be performed with caution, however, because of the deference due the jury in resolving factual issues (ibid at 57).

The Court also begins in this case to spell out the nature of psychiatric expertise and how it is to be distinguished from lay opinion. In relation to the jury's peroga-

tives in dealing with psychiatric testimony, the Court states that its prior holding in *Holloway* (148 F.2d 665)

... is not authority for disregarding expert testimony. It must be considered with the other evidence, not arbitrarily rejected. A jury must not be upheld in arbitrarily convicting of crime (ibid at 59).

This case sets the stage for further refinement of the questions of weight of evidence and burden of proof.

Six months after *Douglas* in April, 1957, when *Blunt v. U. S.* (244 F.2d 355 [1957]) was decided, the court further clarified its views on psychiatric expert testimony. Noting that the trial judge charged that "*The doctor's opinion was not therefore based on actual observation or on actual facts, but on conclusions drawn from an examination held considerably after the commission of the offenses*"³ (ibid at 364) the court said:

As an expert witness, the psychiatrist is permitted to testify to his inferences from facts. His opinions are exactly what is sought. And these opinions may be based upon facts he has himself observed, or facts he has heard others relate, or hypothetical facts presented to him. The purpose of employing an expert witness is to obtain for the jury the type of clinical opinion he is accustomed to form and to rely upon in the practice of his profession. This is what the psychiatric witnesses did in this case. Though their conclusions were not mathematically demonstrable certainties, neither were they mere conjectures, suspicions or hunches.

Because of the trial judge's distorting comments about the psychiatric testimony as well as other prejudicial remarks about the evidence, the case was reversed and remanded for a new trial (provided *Blunt* was found competent to stand re-trial) (15).

When the Court of Appeals reversed and remanded the second conviction of *Stewart* (*Stewart v. U. S.* 247 F.2d 42 [1957]) in a much divided *en banc* opinion, they further clarified their expectations regarding psychiatric testimony. Rejecting a contention by appellant they said,

The rule laid down by *Durham* requires no different examination by the psychiatrist, but

³ Italics are the Court's.

only a different examination of the psychiatrist by the lawyer (*ibid* at 44).

Because of the prosecutor's hints that some of the psychiatric and lay witness testimony about defendant's mental state might be perjured and which . . . are the more prejudicial because their impact on the jury is always more or less strengthened by his official position . . . *Commonwealth v. Clark* 86 Ky. 663, 7 S. W. 155, 156 (1888)" (*ibid* at 46), the divided court reversed and remanded for a new trial.

In *Briscoe v. United States*, 245 F.2d 640 (1957), the nature of psychiatric testimony was discussed and clarified further. The Court notes that the psychiatric experts presented their testimony as conclusions, rather than the observations from whence they drew their conclusions. This case also provides several excellent examples of psychiatrists talking in the language of lawyers, lawyers and judges drawing psychiatric inferences, and even a psychologist making medical conclusions of fact. Judge Bazelon states in his opinion that:

It, by testimony that the accused either was or was not suffering from a "mental disease" or a "mental defect," a psychiatrist would be expressing a judgment that the accused should or should not be acquitted, that would be a legal rather than a medical judgment and would usurp the function of the trier of the facts. While the state of the accused's mental health is a proper subject of medical opinion, no purpose is served by giving the fact trier a doctor's version of a legal opinion. To that end, if the psychiatrists were to testify in terms embodying legal conclusions, the lawyers by examination and cross-examination, would seek to bring out the medical facts. The same is true if the psychiatrists were to testify in such ambiguities as "sound mind" or "unsound mind" (245 F.2d 640, 644).

The *Briscoe* opinion answers the argument that *Durham's* concept of "mental illness" will turn into the same ossified non-entity as M'Naghten's "Right from Wrong." Indeed, it might, but like all word symbols, it must be redefined constantly to maintain contemporary significance. *Durham*, *Briscoe* and other opinions, tend to force such re-definition and re-clarification.

In *Carter v. U. S.* (252 F.2d 608, 617 [1957]) the court stated:

Description and explanation of the origin, development and manifestations of the alleged disease are the chief functions of the expert witness. The chief value of an expert's testimony in this field, as in all other fields, rests upon the material from which his opinion is fashioned and the reasoning by which he progressed from his material to his conclusion; in the explanation of the disease and its dynamics, that is, how it occurred, developed and affected the mental and emotional processes of the defendant; it does not lie in his mere expression of the conclusion.

Herein lies the heart of a common difficulty for psychiatrists, and it is ironic that this advice must come to us from the Court. While courts often badger us for a different kind of information than this, at the same time we psychiatrists all too often forget the nature of the facts to which we are testifying. At the risk of being repetitious, let me say that when we use the labeling words of our profession, it is highly questionable that we are transmitting any information. The word *psychosis* for example may possibly mean something when one psychiatrist says it to another, but it most certainly has no accurate or specific meaning to a layman. On the other hand, a full description of the clinical observations which bring us to our "conclusion," may be very informative to that same layman.

The Court in this case also substantially clarified the relative merits of lay versus expert testimony. They write:

Also obvious upon a moment's reflection is the fact that, while a lay witness's observation of abnormal acts by an accused may be of great value as evidence, a statement that the witness never observed an abnormal act on the part of the accused is of value if, and only if, the witness had prolonged and intimate contact with the accused (252 F.2d 608, 618).

When the divided court affirmed the second conviction of Lyles, (*Lyles v. U. S.* 254 F.2d 725 [1957]) Judges Prettyman and Burger writing for the majority, reiterated the rule that the jury has the right to know and must be told what will happen to the accused if they find him "not guilty by reason of insanity." They also ruled on several technical questions regarding admissibility as evidence, of certain records of past mental illness as well as informa-

competency hearings.

The dissenting opinion in *Lyles*, (written by Bazelon, J.) makes it clear that the conflict among D. C. psychiatrists regarding insanity began in this case. The dissenters argue that the trial judge, when he remarked that Lyles' illness was "sociopathy," implied to the jury that if they found Lyles not responsible and committed him to the hospital according to the *Taylor* rule, he would be released shortly since he could not be mentally ill in the eyes of the hospital psychiatrists. In the light of subsequent developments at St. Elizabeth's regarding this diagnosis, there seems to have been considerable merit to this contention that the trial judge's charge regarding psychiatric evidence, was in fact prejudicial (13). This case is important for the issues which it raised, rather than for those it settled.

The main issues raised on appeal in *Wright v. U. S.* (250 F.2d 4 [1957]) involve the government's "burden of proving beyond a reasonable doubt that Wright was sane," and also the failure of the court to grant certain jury charges to defense. The opinion points out that

the nature and quantum of evidence of sanity which the Government must produce to sustain its burden and take the issue to the jury will vary in different cases. Evidence of sanity which may suffice in a case where the defendant has introduced "some evidence" of insanity may be altogether inadequate in a case where the evidence of insanity is substantial. Before considering the sufficiency of the Government's proof in the instant case, therefore, we must assess the evidence of insanity introduced by the appellant (*ibid* at 7).

This becomes the standard for proof of sanity, after this case.

In this opinion there is also a long citation from *Carter*, and the Court emphasizes its position about lay testimony with the comment that:

Although the testimony of lay witnesses may be competent evidence on the issue of insanity, it does not follow that, in the face of substantial showing of insanity, the Government may send the issue to the jury simply by having two policemen testify, "he looked all right to me." The probative value of any opinion on the issue of insanity depends on

the facts upon which it is based. This is especially true of a lay opinion. (250 F.2d 4, 9-10)

In answer to the Government's argument that some of the psychiatric examinations were conducted too long after the commission of the crime to give experts an adequate basis for their opinions, the Court says,

If the Government feels that psychiatric opinions which come into evidence ought to be based on examinations of greater scope and intensity than has been the practice heretofore, it can and should arrange to have such examinations made *abid* at 9.

This well taken point surely will influence future trial preparation by the Government whenever the possibility of an insanity plea arises. It should be apparent also that this will tend to draw the questions of competency to stand trial and responsibility into closer proximity. Much definition and clarification remains to be done in this area of overlapping policy problems.

Defense argued error in the trial judge's refusal to explain to the jury such things as 1. The meaning of "causal connection" 2. The alternative verdicts at which they could arrive, 3. The kinds of mental illness which would allow them to find the defendant insane (the jury itself requested this information) and 4. A request by defense to charge the jury on the right and wrong question. The failure of the trial judge to grant these requests was a part of the error which caused the Court of Appeals to reverse and remand for retrial.

Williams v. U. S. (250 F.2d 19 [1957]) is an interesting case because of its implications for criminal treatment (16). Dallas Williams is a persistent recidivist who had spent 20 of his 39 years in jail, and whose current offense had been tried 5 times, with 3 appeals. Each of the prior convictions had been reversed because of improper determination of his competency to stand trial. At the time of his third appeal he had already been confined 7 years—the maximum sentence in his first conviction. In this opinion, the Court ordered the trial court to dismiss the indictment because of the Government's failure to give defendant his constitutionally guaranteed right to a

speedy trial. In doing so they say (Bazelon, J.)

Considering the pattern of violence characterizing appellant's behavior since his adolescence and the Government's justifiable concern with his criminal recidivism, commitment of the appellant to a mental hospital might well have been the wisest and most desirable disposition of this case (ibid at 26).

It is open to the Government, however to proceed for a civil commitment under D. C. Code § 21-326, if it considers that, with Williams at large in his present state, "the rights of persons and of property will be jeopardized or the preservation of public peace imperiled and the commission of crime rendered probable" (ibid at 26).

After the *Williams* case there follows a series of cases appealed on such issues as, 1. Proof of sanity in the face of substantial evidence of insanity, 2. A motion to acquit, the jury verdict notwithstanding, and 3. An appeal to set aside a writ of habeas corpus, granted to a man who had been committed following a successful insanity plea. Time does not permit detailed exposition of these cases, although they provide interesting highlights to the general development of these aspects of D. C. law. Distributed among the cases described above there is also a series of cases involving the question of competency to stand trial (17).

By early 1958 the impact of these opinions had begun to filter down to the level of the trial courts and the Court of Appeals' efforts to clarify the law involving the insanity plea began to bear fruit. Early in that year there were several cases in which the trial judge directed a verdict of not guilty by reason of insanity, and several defendants were acquitted by the jury with the same verdict. The final case I shall discuss, was the first one in which a jury found a "pure" sociopath, not guilty by reason of insanity. John Leach (*U. S. v. Leach* Cr. No. 450-57 [1958]) was indicted for robbery, tried in November, 1957, and committed to St. Elizabeths. In April of 1958, he filed a writ of habeas corpus, and the District Court ordered his release. The superintendent of St. Elizabeths appealed this action and in *Overholser v. Leach* (257 F.2d 667 [1958]), the Court sets out the standard for release of a

person following commitment as "not responsible." They state:

The phrase "establishing his eligibility for release," as applied to the special class of which Leach is a member, means something quite different from having one or more psychiatrists say simply that the individual is "sane." There must be freedom from such abnormal mental condition as would make the individual dangerous to himself or the community in the reasonably foreseeable future (ibid at 670).

This is a sweeping standard which raises the same spectre as do the "sex-psychopath laws." The relationship of such a commitment to the availability of treatment, the potential duration of such a commitment, and other similar problems, must await the further development of experience as well as law.

We can see from the foregoing that the Court of Appeals in its decisions since *Durham* has systematically dealt with and clarified a great many of the problems raised by the new test for criminal responsibility. The dire results predicted by many have not come to pass, and the criminal process appears to be proceeding in an orderly, and considerably enlightened manner in this jurisdiction. Though full utilization of the opportunities offered by *Durham* is just beginning, there are definite signs that this rule will facilitate greatly the disposition of criminal offenders in whom there is mental illness. This can lead potentially to a single systematic method for criminal adjudication which will make possible the complete individualization of treatment for offenders. It will leave the test for responsibility in a flexible state where it may be altered and updated constantly as behavioral science knowledge advances. It will put pressure continually upon both prosecution and defense to present their case in language which is communicative to the fact triers; not in magical formulae which no one can really understand.

While no major jurisdiction has yet adopted *Durham*, many have had to exert strong pressure to resist it (18). These courts have gone to great lengths to prove why they should not abandon *M'Naghten*. Psychiatrists should recognize this as the

earliest stage of acceptance, and the successful experiment in the District of Columbia with its progressively developing law should speed this change.

8. See: Weihofen, Henry: *Mental Disorder as a Criminal Defense*. N. Y.: Dennis & Co., pp. 365, 1954. The technique for effecting such a commitment varies from one jurisdiction to another, but is always carried out. To imply to a jury that it will not be done, may be held reversible error.
9. It is stated frequently that the rules of *M'Naghten's Case* reflected the status of psychiatric knowledge of that day, but in fact such is not the case. When Cockburn defended Daniel M'Naghten, he frequently referred to a treatise on criminal insanity written by the eminent American psychiatrist, Isaac Ray. See: Diamond, Bernard: *Isaac Ray and the Trial of Daniel M'Naghten*, Am. J. Psychiat., 112: 651, 1956. To a very considerable extent Ray's views reflected concepts of mental function essentially dynamic in character. For example, see: Ray, Isaac: *Medical Jurisprudence of Insanity*. Boston: Little & Brown Co., 1838, Chapter 6 at page 152. We should recall also that Isaac Ray influenced another important opinion through his close correspondence with Justice Doe of the New Hampshire Supreme Court, which handed down *State v. Pike* in 1870. (49 N. H. 399. Also *State v. Jones*, 50 N. H. 369 [1871]). See: Reik, Louis E.: *The Doe-Ray Correspondence*. Yale L. J., 63: 183, 1953. This early precursor of *Durham* used similar language to its modern counterpart. Merely on the face of this fact, it can hardly be contended that *Durham* exceeds the status of current psychiatric knowledge. It merely catches up with knowledge well known at the time of the *M'Naghten* and *Pike* opinions.

DISCUSSION

CHARLES SAVAGE, M.D. (Palo Alto, Calif.)—The *Durham* decision was greeted with tremendous acclaim 5 years ago by the idealist who saw in it a Bill of Rights for the mentally ill, and by the villain, who as Cicero points out "Inevitably seeks justification for his crime in some natural provision of rights." It was also greeted with grave apprehension by lawyers. The high hopes of the former and the dour expectations of the latter have all been confounded by the

development of the Durham decision.

Dr. Watson has given us a thorough and scholarly analysis of the Durham decision and its development and vicissitudes during the past 5 years. He has rightly stressed the communication difficulties between psychiatrists and lawyers, and the tendency of psychiatrists to speak like lawyers, and of lawyers to speak like psychiatrists. If I were to make any criticism of this paper, it would be that Dr. Watson falls into the same error of which he complains. His paper speaks the language of the law rather than of medicine. I regret that his very thorough analysis could not have included some reference to psychiatric opinion more modern than that of Isaac Ray. But while I have nothing but praise for Dr. Watson's analysis, I have sometimes thought of the Durham case as the worst thing to come out of Washington since the Dred Scott Decision. It arises from the same humanitarian impulse which seeks to resolve a social dilemma by a *tour de force* of judicial legislation. Though widely heralded as bringing legal psychiatry more in line with modern psychology, it actually does no such thing. It is a peculiar mixture of Aristotelian faculty psychology, metaphysics, mysticism, and mediaeval theology. Were I a lawyer I would also hazard the opinion that it is not very good law either.

Dr. Watson has commented on its vagueness. It is indeed vague particularly in the matter of the first test of responsibility: that of mental illness. There are very few people who could not qualify under this test, and they might run the risk of being diagnosed as suffering from the "normal neurosis." Dr. Funkenstein has told us how the people of Burma are predominantly paranoid, and incidentally have a high homicide rate. Would it not perhaps be possible to qualify an entire population under the Durham test of responsibility?

However, as Dr. Watson has shown, this vagueness, which I would characterize as extreme has proven no barrier to its adoption. In extreme cases there will be general agreement among psychiatrists. It is in the borderline cases such as the sociopaths where there will be wide disagreement: the same cases which caused us great difficulty during the old M'Naghten days.

But even if one can get general agreement as to the presence or absence of mental illness, (which is possible, if one can get general agreement as to the definition to be used), there is no possibility of answering the second question posed by the Durham decision: is the crime the product of a mental illness. I can see this question as only sheer mysticism if not madness. How can a crime be the product of a mental illness? Crimes are committed by people, not by mental illnesses. It is as though the mental illness were some daemon residing within the head which mediated some behaviour and not others. As Dr. Weinstein has pointed out, one cannot even tell which part of behaviour is mediated by an epileptic focus.

The Durham decision merely restates the principle of the M'Naghten Decision in different language. Both assume that one is naturally endowed with freedom of the will which may however be overturned temporarily or permanently by illness. Both make implicitly the declaration that if one chooses the evil side of one's own free will, then he may expect the wrath of Judgment Day.

This is hardly consistent with a deterministic scientific view of behaviour. But it is certainly consistent with Judge Bazelon's position which he has stated as follows: "Juries will continue to make *moral judgments* still operating under the fundamental precept that our collective conscience does not allow punishment where it cannot impose blame."

This is neither good sense nor psychology. This hopelessly confuses the laws of the state and the laws of God, which presumably were separated some time ago by Hobbes. It ignores the fact that punishment can be quite effective without any necessity of attaching blame. As Dr. Richard Board of Washington has put it, "Liberalized criteria for establishing criminal responsibility as represented by the Durham decision are but siren songs, luring the psychiatrist from his deterministic science to pose as an expert on theological matters. Where in the range of psychodynamics does moral responsibility suddenly or gradually appear?" Here lies my only quarrel with Dr. Watson. The psy-

chiatrist, when he testifies in a trial of criminal responsibility, *does testify about moral guilt*, whether he likes it or not.

I have stated above why the Durham decision should be grounds for disquietude on the part of any psychiatrist. The grounds for discontent for the villains are contained in the important decision: *Overholser vs. Leach* which is the counterpart to *U. S. vs. Leach* where Leach was found not guilty by reason of insanity due to "pure" sociopathy. *Overholser vs. Leach* established that sociopathy is grounds for continued commitment. I wish Dr. Watson had had more time to devote to this case which is crucial to the development of the Durham decision, and as he says: "is a rather sweeping standard which no doubt raises the same spectre as some of the 'sex psychopath' laws." I suspect that criminals and their lawyers may discover, as a result of this decision, that a short term in a well run prison would be far more salutary than indefinite commitment to a hospital for the criminally insane.

This raises the happy prospect that good may eventually grow out of evil, that the Durham decision, bad as it is, will initiate a series of changes which will lead to its

own abandonment, that not guilty by reason of insanity will disappear as a plea except in capital cases. Then if we could but begin to believe in the lofty moral sentiments that we pay so much attention to, we might obey the fifth commandment and abolish capital punishment, and with it abolish insanity pleas altogether.

When we realize that salting away the sociopath for a long time in a mental hospital is no answer, we may even get around to reforming our penal system. And I can think of no better way to start than to re-read Dr. Solomon's last year's address on the evils of large overcrowded hospitals and recognize that it applies with equal force to prisons.

When this happy event occurs, we can resign from the arena of theology into which Judge Bazelon has cast us as experts, and resume our role as physicians and scientists who may be hopefully able to advise the court on the sentencing and disposition of criminals. The jury could stick to determining matters of fact; the judge could return to the administration of justice. Moral judgments are far too important for men to assess; their assessment should be left to God.

THE PLACEBO EFFECT IN THE HISTORY OF MEDICAL TREATMENT : IMPLICATIONS FOR PSYCHIATRY

ARTHUR K. SHAPIRO, M.D.¹

INTRODUCTION

The interest in the placebo effect has increased considerably in recent years. More articles have appeared in the last 4 years (34 during 1954-1957) than in all previous years combined (22 prior to 1945) (1, 2). Indices, journals, texts and abstract journals are increasingly including the word placebo in their lists of references (1, 2). The word placebo appears more frequently in the title of articles and it is becoming a commonplace in research as it has been a commonplace in medicine for a much longer period of time (3, 4, 5). A placebo control is included in double-blind studies which also are appearing more frequently in scientific literature.

This paper is a shortened version of the first of several papers on the placebo effect (2). Our concern in this paper will be limited primarily to an examination of the historical data. This is important, for as stated by Santayana, "Those who forget the past are destined always to repeat it."

HISTORY AND DEFINITION OF THE WORD PLACEBO

Let us first trace the history of the word placebo (6, 7, 8). It is the first person singular of the future indicative of the Latin verb "to please," the word "placebo" being equivalent to the phrase "I shall please." The first use of the word dates back to at least the 13th century, appearing in the Vespers for the Dead in the Roman Catholic service. It was used in the sense of "I will walk before . . ." or "I will please . . ." It is then found in phrases and nouns by Chaucer and Scott suggesting sycophancy and servility. It is defined as "a commonplace method of medicine" in the 1787 edition of Quincy's Lexicon and in the Philadelphia Medical Dictionary published in 1808 by John Redman Coxe. Pepper (8) points out that this definition may illustrate

the earliest stage of doubt concerning the efficacy of prescriptions of those days, and an approach to the frank admission of a quarter of a century later which appeared in the 1811 edition of Hooper's Medical Dictionary with the definition of the placebo as "an epithet given to any medication adopted more to please than to benefit the patient." Almost all definitions in contemporary medical dictionaries are inadequate. The usual definition, with slight variation, is similar to that appearing in the 1951 Dorland Medical Dictionary (9), where it is defined: "An inactive substance or preparation, formerly given to please or gratify a patient, now also used in controlled studies to determine the efficacy of medicinal substances."

Recent investigators have elaborated further on the characteristics of placebos (3, 5, 11-13). The most widely known type is the "pure placebo." It is an inert substance such as the lactose or sugar tablet and the distilled water or saline injection which is physiologically, biologically and organically inactive. Another more subtle and often unrecognized type is the "impure" or "adulterated placebo" which contains some active ingredient, but which has no effect on the patient's illness. It may contain a truly active substance but be given in inappropriate circumstance or inadequate dosages. The majority of placebos are of this type, and include medication or procedures for every disease and system of the body. A placebo may be a drug which the physician knows to be a placebo, but which the patient believes to be potent. These may be either "pure" or "impure placebos." A second kind is the placebo which both the patient and the physician believe to be potent, but which is really inert. These are usually "impure placebos," the most frequently used type, and probably the most effective. Another type of placebo is that which both the patient and the physician believe in, but which is actually harmful. One need only remember

¹ Albert Einstein College of Medicine and Mental Hygiene Clinic of Bronx Municipal Hospital Center, New York 61, N. Y.

the radium injections given as tonics in a previous era which have caused sarcomas in a number of patients in recent years.

A placebo may be ingested, injected, inserted, inhaled, applied or be any procedure offered with therapeutic intent(8). Thus all treatment procedures can result in a placebo effect(3, 5, 8, 10-14). This may be the only effect, the major effect, a minor effect, or not take effect at all. The placebo effect, if it occurs, may be positive or negative, *e.g.*, the patient getting better or becoming worse(5).

Some of these thoughts have been incorporated in a recent and improved definition of the placebo as, "a preparation containing no medicine (or no medicine related to the complaint) and administered to cause the patient to believe he is receiving treatment"(15).

DEFINITION OF THE PLACEBO EFFECT

For the purposes of this paper, let us define the placebo effect as the psychological, physiological or psychophysiological effect of any medication or procedure given with therapeutic intent, which is independent of or minimally related to the pharmacologic effects of the medication or to the specific effects of the procedure, and which operates through a psychological mechanism.

PRESCIENTIFIC MEDICAL TREATMENT

Medication always appears to have been of importance to man. Sir William Osler (16) felt that the desire to take medicine was one feature which distinguished man from his fellow creatures. It is probable that whatever beneficial effects accrued to man's first medication could only have been due to the placebo effect(13). Of course we do not know anything about the nature of man's first medication, nor anything about the first physician. Historians, however, attribute the earliest portrait of a physician to Cro-Magnon times in the year 20,000 B.C.(17, 18). Obviously this horned, tailed hirsute and animal-like apparition had great psychological effect, and it is likely that the medication used by this physician was principally as a vehicle to enhance the psychological or placebo effect and without any intrinsic merit(13). Al-

though a surgical procedure in our times has much intrinsic merit it also has a profound psychological or placebo effect (13-19). One has only to remember the solemn, tense and magical atmosphere that characterizes the usual lay-dramatization of surgical procedures. It can be said that one common feature that links ancient and modern medicine is the placebo effect(13).

The history of medical treatment, although concordant with scientific progress in general, is at the same time incredible. In ancient Egypt, according to the Ebers Papyrus, in 1500 B.C., patients were often treated with medication such as "lizard's blood, crocodile dung, the teeth of swine, the hoof of an ass, putrid meat and fly specs"(11). No treatments of specific value are found in all the pages of Hippocrates(10). In ancient Babylonia gastric complaints were treated by pouring burning juice of cassia over the patient(20). In the 7th century, Paul of Aegina(21) outlined the use of blood in treatment: pigeon and turtle blood for ocular hematomas and during trephination; owl blood for dyspnea; bat blood for preserving the breasts of virgins; bat, frog, chameleon and dog-tick blood to prevent breast hirsuteness; goat blood for dropsy and kidney stones; domestic fowl blood for cerebral hemorrhages; lamb blood for epilepsy; kid blood for hemoptysis; bear, wild goat, buck goat and bull blood for apostemes; land crocodile blood for visual acuity; duck, stag and goose blood for deadly poisons. It is well-known that bleeding was a very common remedy for a multitude of conditions. Leeches were only one of many methods that were used. In 1827 alone, 33,000,000 leeches were imported into France because domestic supplies were exhausted(22). In the 13th century we read about a cure for gout consisting of oil of skinned puppy, vulture, goose, bear, fox, wax and 7 other substances(20). In the 17th century editions of the London Pharmacopeia(21) we read about the use of worms, lozenges of dried vipers, powders of precious stones, oil of bricks, ants, wolves, spiders and earthworms, fur, feathers, hair, human perspiration, saliva of a fasting man, spider webs, wood lice, moss scraped from the skull of a victim of violent death, crabs'

eyes and claws and human urine. In the 17th and 18th centuries we note the prescription of "hotte horse dung" for ague, goose dung for baldness and sheep dung for gall stones (19).

Despite these useless, abhorrent and often harmful drugs, and the continued prescription of the "flesh of vipers, the spermatie fluid of frogs, horns of deer, animal excretions, holy oil" (12) and other bizarre substances, the physician continued to be a useful, respected and highly honored member of society.

Let us look at some of the most famous medications used by physicians up to the 16th and at times during the 18th centuries (14, 17, 19, 21, 23-29).

Unicorn Horn: The fabled unicorn horn was used to detect and protect against poisons in wines and foods. It usually came from the ivory of the narwhal or elephant. There are records of these horns selling for as high as \$75,000. They disappeared from use in the 17th century.

Bezoar Stones: Bezoar stones came from Arabic medicine to Europe and were used for poisons of all types, melancholia, and as a universal antidote. According to legend, a bezoar stone was the crystallized tear from the eye of a deer bitten by a snake. In reality they were a gall stone or concretion found in the stomachs and intestines of animals such as the goat. These stones were often counterfeited, pebbles being used instead, and there are records of individuals being tried and punished for this offense.

Mandrake: Mandrake was used by the early Babylonians and Hebrews, by Nero and was mentioned by Shakespeare. Its principle use was as an anesthetic and aphrodisiac. According to popular superstition the mandrake shrieked when pulled from the earth and anyone hearing the shriek went mad. To avoid this a dog was tied to the plant and in seeking to escape pulls out the root. As a further precaution a horn is blown to drown out the shriek. Its use as an aphrodisiac is suggested by the existence of male and female mandrakes.

The Royal Touch: The "laying on of hands" as a treatment for illness is one of the oldest and most persistent of methods

which even extends into contemporary times. The Royal Touch, in which a regal and royal personage touched a patient with the King's Evil (usually scrofula but at times extended to all types of illnesses), was perhaps the most famous of such procedures. It first appeared in 300 B.C., entered Europe in 500 A.D. and England in the 11th century. Thomas Aquinas, by testifying to the cure of a page by King Clovis in the 5th century, helped to sanctify the practice. Samuel Johnson was touched as an infant but not cured. Many quarrels occurred over lineage and the right and ability to cure by touching. Patients often were carefully screened and only one treatment per person was allowed (thus decreasing the possibility of failure). King Charles II touched 90,798 patients during 19 years of his reign in the 17th century. Of this ritual, Richard Wiseman, the surgeon to Charles II lamented in his treatise on scrofula, "The weakness of our ability when compared with his majesty's who cureth more in any one year, than all our surgeons of London have done in an age." This practice disappeared in England during the 18th century and in France during the 19th century.

Powdered Mummy: Powdered mummy presumably came from a ground-up mummy in Egypt. It resembled and tasted like rosin, and was used to heal wounds and as an almost universal remedy. Several official conferences complained about the adulteration of the powdered mummy from Egypt (and the impurity of the unicorn horn as well), probably when their effectiveness decreased. Paré, who was influential in undercutting many of these delusory beliefs, replied, "It doesn't make much difference . . . because our French bodies are just as effective . . . , none of them being of any value."

These medications were very expensive and only the wealthy could afford them. Theriac and Mattioli contained up to 63 and 230 ingredients respectively, all of which were worthless. Usnea (the moss scraped from the skull of a hanged criminal), eunuch fat, fly specs, human and animal excretions were some of the more unpalatable drugs. Medical reasoning was primitive: the lungs of a fox, a longwinded

animal, was given to consumptives; the fat of a bear, a hirsute animal, was prescribed for baldness; mistletoe was prescribed for the falling sickness because it grew on the oak and hence cannot fall. Despite the ignorance and superstition, physicians must have benefited their patients because they continued to be held in high esteem.

Consider the treatment by the physicians of his day that Charles II endured:

A pint of blood was extracted from his right arm, and a half-pint from his left shoulder, followed by an emetic, two physics, and an enema comprising fifteen substances: the royal head was then shaved and a blister raised; then a sneezing powder, more emetics, and bleeding, soothing potions, a plaster of pitch and pigeon dung on his feet, potions containing ten different substances, chiefly herbs, finally 40 drops of extract of human skull, and the application of bezoar stone; after which his majesty died (30).

(For a more complete description, see Haggard (17).)

Astute observers of their time, such as Maimonides (31), Montaigne (10) and Molière (24) were able to perceive the serious shortcomings of medical practice. As late as the 17th century, however, a contemporary of Molière, Robert Boyle, the father of modern chemistry, after expunging many questionable remedies from the revised pharmacopoeia, included the sole of an old shoe "worn by some man that walked much" which was to be ground into a powder and taken for stomach ache (25). Oliver Wendell Holmes said as recently as 1860, that if nearly all the drugs then in use "could be sunk to the bottom of the sea it would be all the better for mankind and all the worse for the fishes" (32). Despite this, sick patients continued to submit to purging, puking, poisoning, cutting, cupping, blistering, bleeding, freezing, heating, sweating, leeching and shocking.

One could expand at considerable length on other such examples. Today we know that the effectiveness of these procedures and medications was due to the placebo effect.

In the 17th century cinchona bark, which contains quinine, was introduced as a treatment for febrile infections. Sydenham, by demonstrating that it was only

specific for fever of malarial origin, contributed to the end of Galenism and the beginning of scientific medicine (8, 17, 24, 27, 33). It may be considered that this was the first drug that was not a placebo (8, 10, 11), because previous to this there was no way to distinguish a placebo from a non-placebo (8).

DISCUSSION

If it can be said that scientific medicine truly began only 7 or 8 decades ago (11, 14, 30), we are led to the inescapable conclusion that the history of medical treatment for the most part until relatively recently is the history of the placebo effect, since almost all medications until recently were placebos.

The frequent reference to the importance of the "art of medicine" (13, 18, 34-36) implies an understanding of the placebo effect. This is also true of Hippocrates' observations on the "art of medicine" (37) although none of the drugs used by the latter have proven to be of any use (10). One cannot help notice the rash of treatment methods that successively appear on the medical scene, only to be relegated to limbo and the status of curiosities in the history of medical treatment (11, 18, 36, 38-41). This has led to the famous admonition: "you should treat as many patients as possible with the new drugs while they still have the power to heal." This implies a knowledgeable appreciation of the placebo effect, a statement which has become so famous that it has been attributed to Trousseau (11, 42, 43), Osler (44), Sydenham (45) and Nolan D. C. Lewis (38).

Although medicine was integrally related to the finest scientific, religious, cultural and ethical traditions in most periods of history, and despite the ephemeral and or quite quantitative appearance of drugs or procedures which were truly helpful, one may ask how physicians maintained their positions of honor and respect throughout history in the face of thousands of years of prescribing what we know today to be useless and often dangerous medications? Indeed! this would have been a major accomplishment of the physician were it not for the fact that despite the uselessness of the drugs and procedures,

nevertheless, physicians did help their patients (10, 11).

We are led then to another conclusion: that the potent placebo effect which characterizes the history of medical treatment is related, in some as yet unelucidated way, to the doctor-patient relationship (4, 5, 10, 11, 46-48). Houston (10) views the physician as the therapeutic agent by which cures were effective in the past, since the therapeutic procedures were placebos. Findley (11) says, "... that the physician is a vastly more important institution than the drug store," and that even today, "Despite the scientific achievements of this century the physician himself is still the most important therapeutic agent." It has been aptly observed that the physician's most important therapeutic agent is his medical degree which he receives upon graduation from medical school.

Houston (10) remarks on the many reminders of the historical past in the contemporary successful existence of the nostrum vendors, chiropractors and myriads of other varieties of quackery. He also notes that no one considers applying the principles of osteopathy to animals, where it would certainly fail, because the principles are effective only when they involve a human interpersonal relationship.

To the element of the doctor-patient relationship, we must add the importance of faith which is reflected, in part, by the fact that the best educated, major religious group in the United States is able to deny the rational efficacy of any treatment or medicine and to assign all treatment benefits to faith.

Another factor contributing to the "success" of these physicians in the past must be postulated. Spontaneous recoveries and remissions "can" occur in the course of almost any illness and "may" be unrelated to the administered drug, doctor-patient relationship and placebo effects. It is very difficult, however, to isolate this factor because of the potential placebo effect in every therapeutic relationship. In addition, the belief of the physician and/or the patient that recovery is a consequence of some activity of the physician would tend to increase the effect of placebos in general. Although this factor must be postulated it

does not negate what is thought to be the more important influence of the doctor-patient relationship in the history of medical treatment.

We would have to mention also the importance of enthusiasm, expectation, conviction, suggestibility, personality and psychodynamic factors, and the unconscious and preconscious attitudes of both the doctor and the patient (2). Other factors have been suggested (2). Much research is required in order to delineate the specific factors involved.

IMPLICATIONS FOR PSYCHIATRY

These historic considerations have important implications for, and are clearly applicable to, all research and the evaluation of all therapeutic methods. This is especially true of psychiatry which has inherent factors which maximize placebo effect potentialities. The placebo effect is a notorious concomitant of newly introduced therapeutic methods, and almost all treatment methods used in psychiatry today have been introduced relatively recently. The placebo effect is maximized and determined in part by the character of the doctor-patient relationship. This relationship is particularly close in most methods of psychiatric treatment, and is the major tool in all psychotherapeutic methods of treatment.

Many methodological variables are taken into consideration in contemporary research and evaluation of therapeutic methods. Unfortunately, however, surveys of medical (and other scientific literature) reveal gross inattention to the placebo effect as an important methodological variable (34, 49, 50). This factor requires special attention because it is always present in therapeutic situations and extremely potent in its consequences (5, 8, 10, 13, 51). It requires the use of placebo controls, the double blind procedure, statistical analysis and consultation and concern with other appropriate methodological principles (52).

This paper has emphasized only the tendency to overevaluate the efficacy of therapeutic methods. Although this is the most marked tendency, one must mention also the influence of negative placebo effects contributing to an underevaluation of true

ly helpful therapeutic methods. Occasional records do occur of ancient medicine having stumbled upon useful drugs. The inability, however, to scientifically evaluate the specific usefulness of the drug resulted in its loss to future generations. The ancient Chinese gave ground-up "dragon bones" to children with convulsions(11); burnt sponge, which contains iodine, was used to treat simple goiter(11); an extract of the meadow saffron, which contains colchicine, was used in the treatment of gout in the 6th century(23). In addition, these truly helpful treatments were lost to future generations, in part, because of the placebo effects of other useless medication.

Today we know that negative investigatory attitudes (negative placebo effects in part) can determine negative results. The problem of evaluation can be further complicated. An over enthusiastic investigator may come away with positive results for a great number of conditions, only a few in reality responding to the specific effect of the treatment, the others responding to the non-specific effects stemming from the placebo effect. Another investigator may "fortuitously" study the effect of the treatment on those patients who are positive placebo reactors, and come away with negative results, erroneously rejecting the whole treatment.

Physicians and investigators, to some extent, in one form or another, recognize the widespread existence and potent influence of placebo effects. However, there is a marked tendency for the latter to recognize placebo effects more easily in the work and practice of others than in their own work and practice. This is illustrated by the finding that 3 times as many physicians are of the opinion that they used placebos less frequently than their colleagues(48).

I believe that if we keep these thoughts in mind we will appear as wise 100 years from now as do the compilers of the *Paris Pharmacologia* of a century ago who said,

What pledge can be afforded that the boasted remedies of the present day will not, like their predecessors, fall into disrepute, and in their turn serve only as a humiliating memorial of the credulity and infatuation of the physicians who recommended and prescribed them (53).

SUMMARY

A brief history of the word placebo was presented and the placebo effect was defined. Characteristic examples of prescientific medical treatment were described. The following conclusions were reached: The normative history of medical treatment until relatively recently is the history of the placebo effect. Although physicians prescribed what we now know to be useless and often dangerous medications and procedures for thousands of years, they maintained their positions of honor and respect throughout history because they did help their patients. This was possible because of the potent placebo effect. The placebo effect is related to the doctor-patient relationship and a number of other factors derived from this relationship. The placebo effect is maximized by the closeness of the doctor-patient relationship in psychiatric treatment. Therapeutic efficacy should be studied and evaluated in the light of the methodological principles stemming from this knowledge.

DRUGS AND PSYCHOTHERAPY¹

PAUL H. HOCH, M.D.²

When we discuss the relationship of drugs to psychotherapy we must decide first when drugs should be used, when psychotherapy should be used, and when the use of a combination of both is indicated. Today drugs are used extensively in the treatment of the psychoses, and especially in schizophrenia, but also increasingly in depressions. The kind of treatment to be applied will have to be decided based upon the clinical manifestations of each individual case. Generally speaking, a psychiatrist will use drugs in the major mental disorders and psychotherapy as an adjunct, whereas in the psychoneuroses he will use psychotherapy as the main treatment and if necessary, drugs as an adjunct. However, the indications as to when drugs should be employed and when not are not clearly drawn. In major mental disorders where it is far more difficult to reach the patient and where the symptoms overwhelm him and prevent him from functioning, the use of drugs is indicated much more than in most patients who have adjusted and are able to maintain their professional and social activities.

Drugs are now used extensively in schizophrenic patients in public mental hospitals. They usually receive one or another of the tranquilizing drugs and many show an impressive improvement. The amount of psychotherapy these patients receive is usually limited and is confined to reassurance or a discussion of their problems with the therapist. In many mental hospitals a so-called therapeutic milieu is organized where the personnel in general partakes in some activity with, or in relationship to, the patient. In a broader sense this can be considered psychotherapeutic, but, of course, none can be labelled as organized psychotherapy. A very few patients in public mental hospitals can receive a systemic and organized form of psychotherapy on an individual level.

¹ Read at the 115th annual meeting of The American Psychiatric Association, Philadelphia, Pa., April 27-May 1, 1959.

² Commissioner of Mental Hygiene, State of New York; Professor of Clinical Psychiatry, College of Physicians and Surgeons, Columbia University.

Of course many could participate in group therapy, but nevertheless a large number of patients receive drug therapy with little psychotherapy.

This immediately brings up the important question as to how much psychotherapy is needed for psychotic patients being treated with drugs. To what extent can drugs replace psychotherapy and vice versa? The psychotherapy of the functional psychoses rests on the shaky assumption that these disorders are of psychic origin and therefore, similar to the neuroses, should be treated with psychotherapy. Application of psychotherapy in the functional psychoses is very complicated in public hospitals. Its reach is limited and the most difficult problem is the lack of adequate personnel which makes it an impossible undertaking. The statistics indicate that many schizophrenics show marked improvement and even an elimination of symptoms with drug treatments alone. On the other hand, the relapse rate of such patients is quite high, reaching approximately 30%. However, if they receive psychotherapy in addition to the drug treatment this relapse rate can be cut in half. It appears there are schizophrenic patients who have the ego strength to take over when the drugs reduce the gross psychotic state and who are able to adjust to different environmental situations. In a considerable number of schizophrenics, however, after eliminating the gross symptomatology of the disorder, we still see many adaptational difficulties remaining in relationship to the environment. They often have conflicts, feelings of inferiority, inability to formulate goals, motivational confusion, ambivalence and contradictions. These patients benefit a great deal from psychotherapy.

The problem usually is not mentioned as to what extent psychotherapy can be applied in schizophrenic patients who are being treated with drugs. Seemingly this is not a great problem, most likely because the goal of the therapy is not a reconstructive one and therefore the therapist does not feel that the administration of the drug

interferes to any large extent with the psychotherapeutic process. The role of drugs in these cases is not clearly perceived but it is generally assumed that they suppress some of the symptomatology of the patient which interferes with psychotherapy and therefore makes the patient more amenable to such an approach. I may add there are some physicians who feel that if there is enough skilled personnel available, these patients do not need drugs and the reduction of the symptomatology can be accomplished by other means. Some investigators clearly claim that if you have enough personnel, drugs can be replaced and of course it is also true to some extent that drugs can replace personnel. There is definitely an overlap. This is always present if we manipulate the human psyche which is open to influence on many levels and it is possible to approach it psychotherapeutically and at the same time, chemically. The issue that will have to be discussed is which is more efficient and which is more feasible in a given case. However, we should not use vague or glib generalizations.

We feel that the combination of drug treatment and psychotherapy is of special importance in schizophrenic patients, many of whom are treated in outpatient setups and in private practice. Many of these schizophrenic patients are very anxious, overwhelmed by their conflicts and most of the time only partially able to be in contact with the therapist. In most of these patients many ego supportive measures have to be applied. Up to a point these supportive measures can be replaced by drugs. The reduction of anxiety and the feeling of better functioning helps psychotherapy considerably. The reduction or elimination of secondary symptoms such as hallucinations and illusions also fosters the psychotherapeutic attempts because these patients are difficult to approach and influence psychotherapeutically during the time they show florid symptoms.

It is necessary to keep many patients who need some psychotherapeutic help on a maintenance dose of tranquilizing drugs. I have been especially impressed by the fact that in these patients drug therapy and psychotherapy are complementary to each other instead of being antagonistic. In these

patients the use of drugs has to be adjusted to the psychotherapy. A patient on tranquilizing drugs may show less initiative and drive, but not if the drug is used in its proper dosage; and because the patient is less anxious and perturbed he is able to utilize psychotherapeutic assistance far better than before the administration of the drug. The ability of these patients to utilize psychotherapy under drug treatment is in sharp contrast to the time when no drug was available. The ego supportive measures which had to be carried out, the reassurance which had to be given, the different maneuvers in which the therapist had to engage to overcome the patient's anxiety and preoccupations can be eliminated by the drug in many instances. I feel the combination of drugs and psychotherapy will have its main effective application in schizophrenic patients, in the pseudoneurotic schizophrenic group, and in depressions. After being treated by drugs some will be able to function, but there will be those who will need psychotherapy even though the drugs have reduced or eliminated the feelings of depression.

One of the most controversial points is the use of the drugs in the treatment of the psychoneuroses. I believe that the great resistance in some psychiatric circles to the use of these drugs is essentially based on the psychiatrist's experiences with neurotic patients. I feel that every case has to be individually evaluated. It is obvious that many psychoneurotic patients should be treated without any drug adjuvant because the treatment would not be facilitated if drugs were to be administered. We must distinguish, however, between psychoneurotic patients who function relatively well and are not markedly crippled by the intensity of the different psychoneurotic symptoms. Nevertheless, there are patients—for instance, some phobic ones, where the anxiety is so intense that the patient is quite handicapped and is not able to function even relatively well—when the use of the drugs eliminates the anxiety to such a degree that they are more comfortable and are able to partake of psychotherapy.

Some physicians have expressed the fear that if such patients are rendered comfort-

able by the drug they would lack motivation for psychotherapy. I have not seen this happen. Most of these patients, even though they were more comfortable with the drug, wanted to have psychotherapy and were quite satisfied when the drug was gradually reduced or eliminated. In many instances where the patient only undertakes the drug therapy and does not want psychotherapy the motives are not so much the patient's lack of interest in psychotherapy, as his inability to afford it. In such situations, of course, the patient tries to be content with the use of the drug alone. Occasionally he also may be advised that the drug will take care of all his problems and therefore he does not require any other help. However, most of these patients are aware of the fact that if the anxiety or some other of his symptoms are quantitatively reduced by the drug they still have problems which, so to say, qualitatively speaking, can be adjusted only by discussing some of these problems with the therapist. I believe that this is probably the most important point which can be brought out in relationship to combined treatment. The tranquilizing drugs are able to reduce the amount of anxiety and sensory and proprioceptive bombardment to a level where the patient is able to cope with them. In some patients the reduction of the anxiety and the elimination of the preoccupations permits him to function, but in others, qualitatively speaking, many adjustment problems still remain which the drug does not automatically eliminate and where psychotherapy should be applied. The amount of psychotherapy in these patients is of individual difference and should be regulated in the same manner that the quantity of the drug is regulated in relationship to their needs.

The use of drugs in psychoneurotic patients encounters two main objections: first, that the use of the drug interferes with the transference relationship, and second, that the effects and probable side effects of these drugs interfere negatively with the psychotherapy. I do not believe that the use of a drug necessarily interferes with the transference relationship. I actually feel that if the transference relationship is a good one, the introduction of a drug, even

if it leads to some complications, does not disrupt the patient's relationship to the therapist. The patient feels that every weapon at the disposal of the therapist is used to reduce his symptoms and to help him. Many patients are very appreciative of the fact that their considerable suffering is made more bearable. This usually leads to an enhancement of the transference of the relationship and not the opposite. The idea that the patient has to be profoundly uncomfortable for effective psychotherapy is an old shibboleth which has never been proven and which should be carefully re-examined in the light of newer knowledge. I do not believe that theoretical ballast of this sort should be carried out year after year without the re-examination of the correctness of the foundations.

I may add that here we are discussing psychotherapy and not psychoanalysis. I am sure that even in analytic treatment, drugs can be used if necessary, but providing we assume this would not be "correct" in psychoanalytically treated cases, this prohibition surely does not apply to psychotherapy in general. The question of using or not using a drug in combination with psychotherapy has to be individualized. In my observations I often found that the refusal to combine treatments was not based as much on preconceptions (which in many instances are obvious rationalizations), as on the fact that the therapist has lost touch with these methods and does not know how to give the drugs or is fearful in working in this therapeutic field because of lost proficiency. Advances in medicine are made every day. A physician has the obligation to assimilate the new and connect it with the old. This is sometimes difficult and often the position is taken that everything new is valueless. In my opinion this position is equally as bad as the enthusiastic and uncritical acceptance of every new therapeutic agent. The latter is usually far more often castigated, but this does not mean that the ultra conservative position is the correct one.

The question is often raised how psychotherapy should be integrated with drug therapy from a technical point of view. This has to be approached in the same manner as other treatments based on the indi-

vidual symptomatology of the patient. Nevertheless some general comments can be made. Mistakes are often made in the treatment of these patients in that the drug therapy is entrusted to one physician and the psychotherapy is done by another. The handling of the patient by two therapists who do not fully coordinate these therapies confuses the patient and does not provide him with help. It is rather common that the patient tries to "trap" his therapists into complicating statements, interpretations and recommendations. This, of course, interferes seriously with therapy. I do not believe that the treatment of a patient can be entrusted, so to say, to a committee. I strongly feel that it is preferable if the drug therapy and the psychotherapy are in the hands of one person to avoid the above-mentioned difficulties. In addition the effect of the drug on the patient and the patient's comments on drug action are very important in psychotherapy. The therapist prescribing the drug is then constantly aware of the subtle emotional response of the patient. I do not feel that combining drug therapy with psychotherapy is very difficult provided the therapist acquires a certain amount of working knowledge on the action of these drugs. Usually drugs can be given in amounts which will control the distress and anxiety of the patient. It should not be given in such amounts that the patient's anxiety and tension are completely eliminated. At times the patient will bring up some discussion about the drug and its effects, but in my experience this is only in the beginning of the treatment or perhaps when a change of medication is prescribed.

The use of drugs in psychoneurotic patients may encounter difficulties if side effects on a physical or mental level appear which may affect the treatment. I believe that this is one of the reasons why some psychiatrists do not like to employ drugs in conjunction with psychotherapy. However,

it must be considered that patients with deep rooted anxiety do not respond to therapy quickly and some of them are treated for a long time unsuccessfully. I believe that the patient's faith in the treatment and in the therapist also becomes impaired and in my observations this impairment in a therapeutic relationship is far worse than if the patient develops side effects from a drug which in most instances can be controlled quickly by reducing the dosage or by changing the medication. In addition to the physical complications that some of these drugs can produce we should be aware that there are also psychic side effects. For instance, some of the patients develop feelings of depersonalization, feelings of lethargy and weakness, and in some patients on higher dosages a sensation of restlessness appears. However, all these feelings disappear rapidly when the dosage is reduced. These complications can be readily observed if the patient has regular psychotherapeutic sessions and I do not believe that these complications should be overemphasized or made to appear as too complicated and difficult to handle to rationalize the position that no drugs should be used in conjunction with psychotherapy.

SUMMARY

In summary, I feel there are those cases where drugs can be effectively combined with psychotherapy without detriment to the treatment situation. In fact very often therapy is enhanced if such an integrated approach is used with these patients. Generalizations of do's and don'ts are not applicable. Each patient is a problem in himself. The decision of whether or not to use drugs in connection with psychotherapy should be based on well-conceived clinical judgment. More attention must be paid to such integrated treatment by experts in the field of psychotherapy than has been until recently.

SERUM TOXICITY IN VARIOUS PSYCHIATRIC DISORDERS

JOSEPH WORTIS, M.D.²

INTRODUCTION

Some years ago I became interested in the effect of blood and serum on brain oxidations because blood transfusions seemed to revive patients in irreversible insulin coma. In work published in 1944 I reported that the addition of a small amount of serum (0.25 cc.) to the Krebs-Ringer phosphate glucose solution in a Barcroft-Warburg manometer served to maintain oxidations at a linear rate for as long as 12 hours. Without the addition of the serum, oxidative activity lapsed at about 8 hours. Since recent literature has been suggesting the possibility that the serum in both phenylketonuria and in schizophrenia might be toxic, the present experiments were initiated to determine what effect serum drawn from various patient groups might have on brain oxidative activity.

METHOD

Fresh minced rat brain from 250 gm. white rats was immersed in 2 cc. of Krebs-Ringer phosphate solution containing 200 mgm.% of glucose buffered at Ph 7.38, to which 1 cc. of serum was added. The oxygen uptake at the end of a 2-hour period was measured and calculated on the basis of mm.3 O₂ per mg. of tissue net weight. Ph readings at the end of the run were almost invariably 8.1 to 8.4, due no doubt to loss of CO₂ from the serum. Since the oxidative activity of brain slices, unlike suspensions, is not affected by Ph changes of this range, it is likely the minced brain was similarly unaffected. At any rate, since this was a constant factor in all experiments, the possible depressant effect of this Ph shift on respiratory activity does not impair the comparative significance of the values. The control sera were recruited from a miscellany of cases, including serum specimens taken for pre-marital serological

study, casual specimens sent to the biochemistry laboratories from the general hospital or surgical ward, and from cases of psychopathy, neuroses, conduct disorders, reading disability, epilepsy, delinquency, and chronic brain syndrome. Though the sera for pre-marital testing had been inactivated at 56° C. for 30 minutes, no differences were found between these and other casual specimens, and no differences were found between children and adults, so that all of these together comprised the control group. Specimens from

MAXIMUM ENHANCEMENT OF OXIDATIVE ACTIVITY IS ACHIEVED BY THE ADDITION OF 1.0 CC. OF SERUM.

FIG. 2
DISTRIBUTION OF VALUES FOR MM.³ OF O₂ UPTAKE AT END OF TWO HOUR PERIOD, USING 1 CC. OF SERUM OF CONTROLS. DOTS INDICATE MEAN VALUES.

¹ Presented before the Society of Biological Psychiatry, San Francisco, Calif., May 11, 1958.

² From the Division of Pediatric Psychiatry, Department of Pediatrics, Jewish Hospital of Brooklyn. This work was supported by the M. J. Solomon Research Fund and by an Anonymous Donor.

other psychiatric patients were secured from the Brooklyn State Hospital, Kings County Psychiatric Hospital, Willowbrook State School, and Letchworth Village.³ Most specimens were refrigerated several days before use. Almost all schizophrenic subjects were adult; two-thirds of the mongoloid and phenylketonuric cases were adult. Unless the quantity of serum allowed at least 2 samples to be tested with good correspondence in the results, the data were not used; most data are based on the average of 3 specimens checked against 2 thermobarometers. In a few instances only 2 of the 3 manometer readings were averaged, if the 3rd manometer reading varied beyond 33% of the average of the other two, so that a technical fault—such as a leak—could be reasonably suspected.

FIG. 3

DISTRIBUTION OF VALUES FOR O₂ UPTAKE FOR A TWO HOUR PERIOD, USING SERUM FROM VARIOUS GROUPS OF SUBJECTS.

RESULTS

No depressant effect was found with schizophrenic serum, though 5 of 6 catatonic patients had low values. Under chlorpromazine medication the values rose, especially in those patients receiving 100 mg. or more per day. Alcoholics and mongoloid subjects showed no change. A depressant effect on the oxidative rate was found when phenylketonuric serum was

FIG. 4

DISTRIBUTION OF O₂ UPTAKE VALUES WHEN MONGOLOID AND PHENYLKETONURIC SERUM WAS USED.

used, as shown in Figure 4. Phenylketonuric subjects taking chlorpromazine had somewhat elevated values, and were excluded from the series. For the remaining phenylketonuric group the mean oxygen uptake at the end of 2 hours was 3.5, with a standard deviation of .312. The mean and standard deviation for the control group were 3.7 and .427, respectively. The *t* value of the difference between the means is 2.15 and this is statistically significant beyond the .05 level. A similar depressant effect was found when 40 to 80 mg.% of DL- β -phenylalanine was added to normal serum, but other essential amino acids, such as L-tryptophane, DL-methionine, DL-threonine, L-lysine, and L-histidine all produced similar depressant effects in these concentrations.⁴

DISCUSSION AND SUMMARY

The serum of schizophrenic, alcoholic, and mongoloid patients had no inhibiting effect on the respiratory activity of surviving rat brain. The serum of patients treated with chlorpromazine enhanced the respiratory activity. A slight tendency to elevated values found in recently admitted schizophrenic adults who were not taking chlorpromazine may be due to prior medication before admission. Phenylketonuric serum depressed brain oxidations, though a similar effect was induced by racemic phenylala-

³ Thanks are due to Louis Schneider, the late Eric Brown, and Eugene Jackim for very helpful technical assistance. I would also like to express my appreciation to Drs. Jervis, Jacobs, Engelhardt and Beckenstein, of Letchworth Village, Willowbrook, Kings County and Brooklyn State Hospitals for their friendly cooperation.

⁴ Current work (E. Jackim and J. Wortis: unpublished data) indicates that only the D-phenylalanine exercises a depressant effect. Since only L-phenylalanine is involved in these physiological derangements it is altogether unlikely that the depressant action of the serum is due merely to the presence of phenylalanine.

FIG. 5

THE DEPRESSANT EFFECT OF L-TRYPTOPHANE ON RAT BRAIN OXIDATIONS IN A KREBS-RINGER-GLUCOSE-PHOSPHATE MEDIUM CONTAINING 1 CC. OF NORMAL SERUM.

nine in concentrations above 40 mg.% as well as by other essential amino acids. It has been suggested that the depressant action of various amino acids may be due not to a direct effect of the amino acids, but to aldehyde formation. It has also been

known for a long time that a number of toxic amines such as tyramine, phenylethylamine, mescaline, indole and skatol, all inhibit brain oxidations.

The observed phenomenon may explain the general depression of brain oxidations found in vivo in phenylketonuria by Himwich and Fazekas. The low cerebral metabolic rate found in mongoloid children in vivo by these authors may be due to the brain pathology associated with the condition.

CLINICAL FINDINGS IN THE USE OF TOFRANIL IN DEPRESSIVE AND OTHER PSYCHIATRIC STATES—

BENJAMIN POLLACK, M.D.¹

Roland Kuhn(1) of Zurich, Switzerland, reporting a large series of cases with promising results in the use of Tofranil in the treatment of depressive states, has indicated that this drug is more or less a specific anti-depressive drug although not primarily a stimulant and not a monamine oxidase inhibitor. To date there has been no satisfactory replacement for electroshock therapy in the typical depressive state. The discovery of a drug which would be helpful in such conditions would be of paramount importance, and would permit more extensive treatment in the psychiatrist's office and avoid the necessity for hospitalization. The interest produced by iproniazid and other monamine oxidase inhibitors has furthered the research in this field in an attempt to elaborate a compound which would be free of dangerous complications.

Tofranil(2), known also as imipramine and G 22355, is a recently synthesized psychotherapeutic agent which has now had fairly extensive trials in Europe and more recently in this country. The mode of action of this drug is not quite clear, except for its central nervous system action. It is, however, not essentially a stimulant but in exceedingly high doses in animals can cause tremors, rigidity and respiratory arrest. To do so it is necessary to use doses 20 to 30 times the therapeutic dose used in clinical treatment. This drug produces only a slight potentiation of barbiturates and little or no hypothermic effect. In animals there is evidence of some anti-convulsive effect which protects against metrazol and electroshock in animals when used in very high doses, but here again in humans electroshock can be given readily with little or no change in the dose. It does not increase norepinephrine or serotonin in the brain and is not a monamine oxidase inhibitor. There are some slight peripheral anesthetic qualities and it may therefore produce some peripheral paresthesias or some slight anesthesia of the cornea. Forty percent is

excreted as 2 metabolites in the urine and less than 2% is excreted unchanged. It is rapidly absorbed and it likewise disappears from the body in 24 hours. The Forrester reagent test of the urine is negative. It has no influence on conditioned responses.

Long-term observations with injections in animals of huge doses have not produced hematological or hepatic changes. The lethal dose in animals is estimated as somewhere between 400 and 1200 mgs. per kilo which, of course, would far exceed the clinical dosage, so that there is a very wide margin of safety. It would appear that it is absorbed almost as rapidly orally as parenterally. It can be used both intramuscularly and intravenously, but in the former it is quite irritating.

Its formula resembles that of promazine in which the sulphur atom has been replaced by a dimethyl chain. (Graph 1)

The use of Tofranil was first begun at the Rochester State Hospital in September 1958, 6 months ago. Since this was a new drug which had had few clinical trials in this country, an attempt was made to ascertain its usefulness by giving it not only to patients suffering from various depressions but to those who had a variety of other mental illnesses. Approximately 273 patients are involved in the results. These patients consist of acute and chronic disorders. The drug was administered to practically every newly admitted patient who was suffering from depressive symptoms without regard to the diagnosis. It was also used for various schizophrenic conditions and organic conditions, particularly where there were elements of anxiety or depression. The diagnoses of the treated cases are shown in Table 1.

Treatment was given in various parts of the hospital, and this report is a compilation of the observations of many of the personnel from the various services. For the most part, the patients were treated with relatively low doses of 25 mgs. of Tofranil t.i.d., particularly in the acute cases and with 50 mgs. t.i.d. in the more

chronic cases. It was readily determined that there was a direct relationship between the dosage and the intensity and frequency of side effects. Side effects increased proportionately with age, and many were noted, particularly in patients 60 years of

age and over. In the younger group relatively few side effects were noted. Except for dizziness, side effects were almost infrequent in dosages of 75 mgs. and under, and more frequent in dosages between 75 to 200 mgs. Most of the side effects were more annoying than dangerous and consisted of dryness of the mouth, perspiration, tremors, especially of the upper extremities, dizziness and occasional blurred vision, and in some patients some tendency to gastrointestinal disturbances. Some patients complained of marked constipation, but in the author's experiences this was not as prominent a symptom as reported by other investigators. Increased agitation occurred in a small number of patients. Because of this, certain of the treatment schedules included the use of both tranquilizers, such as Thorazine, and stimulants such as Ritalin. With the combination of such drugs it is, of course, much more difficult to evaluate the role of Tofranil. There did not appear to be any particular tendency toward hypotensive attacks with this drug, in spite of the complaints of dizziness which apparently are due to other causes as is vertigo. One serious side effect which has not been reported in the literature is the factor of sudden falls which occur apparently only in treated patients who are 60 or over. These are of a peculiar type in that the patient falls without any prior warning or previous episode of dizziness or vertigo. Because of this he may fall

suddenly as a dead weight with possible consequent injuries. Such falls occurred only in patients who were receiving Tofranil in doses in excess of 75 mgs. per day, and were entirely abolished in dosages below this level. A further peculiarity is that the patients are amazed to find themselves suddenly falling. There is no loss of consciousness nor do the falls appear to be due to hypotensive episodes as no particular alteration in blood pressure can be seen in such individuals. Experimentally, it has been reported that Tofranil may upset the carotid sinus mechanism in animals, and this may perhaps offer an explanation for such falls. It can be seen from Table 3 that dizziness and tremors consti-

cause states of euphoria which may reverse the depressive states into manic excitements. There is a greater tendency to a more normal type of feeling so that the patient does not feel stimulated or over-active. This is an important differential since it permits a patient to act with good judgment and to partake of social activities in an acceptable manner.

CLINICAL RESULTS

All research workers who used this drug initially were unanimous in the conclusion that, unlike many other psychopharmacological agents, it specifically affects depressive conditions and has very little effect on paranoid states or disturbed behavior, particularly in schizophrenics. This initial impression is rather intriguing and a unique finding, and should be investigated more widely for a longer period of time. Since depressive states frequently have a natural tendency towards recovery, it is much more difficult to evaluate the results produced by Tofranil as compared to the results noted in the use of phenothiazines in schizophrenics and allied conditions. It would, however, appear that proportionately a larger number of patients are improved clinically than could be anticipated without the drug and that such improvement occurs more rapidly. The specificity of the effect can also be demonstrated in that in early cases the patient will quickly relapse if the drug is removed since there is very little storage of this drug in the body beyond 24 hours. Its effect is much less spectacular than the results produced by ECT, but is much more acceptable to most patients. It would appear evident that the greatest value of the drug is in conditions of pure retarded depression which are unassociated with somatic complaints, agitation or paranoid tendencies. The greater frequency or intensity of such symptoms accompanying the depression will, as a rule, lessen the therapeutic benefits of Tofranil. However, it seems to be almost impossible to point with any degree of consistency to certain target symptoms which are affected most promptly and effectively by this medication. Endogenous depressions appear to do well and a number of agitated depressions respond quite well. However,

tuted the largest number of side effects. These, however, are seldom of sufficient severity to require discontinuing the medication since lowering the dosage, as a rule, will abolish these symptoms. The literature contains two reports of the occurrence of jaundice with the use of Tofranil. So far no cases of agranulocytosis has been reported. Unlike Marsilid, Tofranil does not

in some it often is necessary to use certain other drugs such as Thorazine or Ritalin. Tofranil appears to remove the depressive elements and to free anxiety which requires control by tranquilizers. These are best given at night in a single dose, to promote sleep and to avoid lethargy or drowsiness during the daytime. When the drug is effective, results may be seen as early as the first or second day and usually within a week. Occasionally little effect will be noted for 2 or 3 weeks. One articulate, intelligent patient who had had much experience with the effects of other drugs stated in speaking of Tofranil that its effect is "sneaky; without realizing it you suddenly find yourself doing and enjoying things which you were too tired to do the day before." There is no dramatic change but many of the patients state that they feel normal or that they feel good. There appears to be a general release of the depressive attitudes even though at the same time some patients may continue to talk of various feelings of guilt or sinfulness. In this connection the drug may relax the patient sufficiently so that they are more responsive and available for concomitant psychotherapy. They gradually become more remote or detached from their thought content with subsequent improvement in affect. The drug was used in association with ECT without any particular increase in side effects or complications. It appeared to be also effective in recurrent depression which previously had been treated by electroshock. It was found that the use of Tofranil in such cases diminished the frequency of relapses.

The drug was also used on 60 schizophrenics, many of whom had depressions associated with paranoid ideas. Others were catatonics or withdrawn or mute. It was quickly evident that Tofranil was not of great value in schizophrenics and in fact in many cases was contraindicated because at least half of them became worse. It would appear that a compensated paranoid schizophrenic who is given this drug may be relieved of depression or anxiety, but the paranoid elements become exaggerated. Such patients became much more disturbed, suspicious, hostile and aggressive.

An example of this reaction was a male patient who prior to treatment had been somewhat surly and inappropriate, hostile, suspicious, occasionally defiant, but on the whole able to control his symptoms and in general quite cooperative. He received 100 mgm. of Tofranil and within a week became restless, agitated, sullen, argumentative, combative and unable to control the symptoms or the emotional state which previously was held under some degree of control.

A number of depressions in arteriosclerotics and seniles were treated with rather impressive results. In about 50% to 65% of the patients the depression cleared or became ameliorated. The organic symptoms of confusion and disorientation, of course were not affected. It must be realized, however, that there are many patients in the older age group who develop depression without precipitating organic etiology. This type appears to respond quite well to the use of this drug.

It must again be emphasized that in the older person the drug should not be used in large doses, an effective dose usually varying between 25 and 75 mgm.

The results of treatment are briefly summarized in Tables 4-7. On the reception service most of the patients treated were either readmissions or acute admissions and most of them were suffering from an involutional psychosis, a manic-depressive depression or an acute psychoneurosis. There were also a few depressions associated with psychosis with cerebral arteriosclerosis.

A group of seniles or arteriosclerotic patients were selected from a chronic area for treatment for a single symptom which they commonly displayed, namely depression. For the 57 in this group, the results are shown in Table 6.

It is, of course realized that the results quoted in this group are based upon the improvement in only one symptom, namely depression.

These tables vividly display the specificity of this drug in treatment and indicate why it has been labelled by many research workers as an anti-depressive drug which produces promptly or gradually a change in the depressive state. Some patients fail to respond to treatment and show no improvement in their depression and it seems impossible to determine the difference among patients since they apparently display the same type of symptom. No study was made of the environmental situations or previous personality patterns. Table 7 includes a number of private patients seen in office practice by some of the psychiatrists participating in this study.

There are sufficient indications, however, that Tofranil is a useful drug and that

somewhere between 50% and 70% of patients displaying depressive symptoms will improve. Where no improvement occurred, a tranquilizer, usually chlorpromazine, and a stimulant, usually Ritalin, were added to the treatment schedule. This combined form of treatment resulted in 10% higher improvement rate than when Tofranil was used alone. When the depression failed to clear adequately or to sufficient degree, an occasional electric shock was given in conjunction with the use of Tofranil. Indications are that the addition of Tofranil to such therapy will reduce the relapse rate and permit a more stable course. The use of this drug has reduced the need for ECT to almost the vanishing point, except for an occasional concurrent shock treatment.

Of the patients treated who are now out of the hospital, (approximately 50) the vast majority of pure depressive states were released from the hospital within one or two months. It is interesting to note that some of these include patients who failed to respond to electric shock previously or whose improvement lasted for only a short period of time.

SUMMARY

1. Preliminary observation would indicate that Tofranil is a useful drug in the treatment of depressive states. It is not a tranquilizer and, therefore, is of little value in other conditions. It is a promising drug which can be used as an anti-depressant. However, its indication and scope must be studied for a longer period to determine what symptoms respond best to it.

TABLE 7
RESULTS OF TOFRANIL THERAPY IN 273 ACUTE AND CHRONIC PATIENTS

Diagnosis	Much Improved	Improved	Unimproved or worse
All treated patients	56%	16%	28%
Involuntal Depression	58%	16%	26%
(a) Without Agitation	58%	17%	25%
(b) With Agitation	60%	13%	27%
(c) Combined with Chlorpromazine	63%	18%	19%
(d) Combined with Chlorpromazine and Ritalin	69%	8%	23%
Manic-Depressive	70%	13%	17%
Reactive Depression	72%	7%	21%
Organic and Senile Depression	56%	14%	30%
Psychoneurotic Depression	59%	14%	27%
Schizophrenia	14%	24%	62%

2. The effect of Tofrānil in many patients can be increased by the concomitant use of a tranquilizer or a stimulant. In a number of patients Tofrānil, by removing the depressive elements, frees and exaggerates anxiety.

3. It can be used in combination with electric shock or after electric shock as a maintenance dose.

4. It is of little value in the treatment of schizophrenics and in paranoid types may often aggravate the condition and break down an unstable equilibrium to which the patient has become adjusted.

5. The combined use of Tofrānil and a tranquilizer is helpful in certain psychoneurotic states, associated with anxiety or with reactive depressions.

6. It is of value in the treatment of depressions occurring in the older age group.

7. High doses are unnecessary and the effective range is somewhere between 75 and 150 mgm. per day.

8. For the most part, side effects are minimal, particularly in the younger age group. As one approaches the older age group, the frequency of such side effects increases, but usually they are more uncomfortable than serious. In patients over 60 there may be a tendency to sudden falls which occur without warning. It is recommended that in older patients the dosage be limited to 75 mgm. or less.

9. Side effects can usually be reduced in frequency or intensity by a reduction in the dosage.

10. Long-term use of the drug is apparently necessary as patients may relapse, at least in the early stages when the drug is prematurely removed. Since the drug is rapidly excreted, it is necessary to give the medication 3 times a day.

EFFECT OF TRIFLUOPERAZINE ON AUDITORY / HALLUCINATIONS IN SCHIZOPHRENICS

WALTER KRUSE, M.D.¹

Five years' experience with neuroleptic therapy has convinced us beyond any reasonable doubt that these drugs are effective. Yet, their mode of action is still essentially unknown. We believe that one way to a better understanding of the therapeutic process in modern drug treatment is the detailed study of psychopathological observations made in patients that receive the new medications. Trifluoperazine,² in our experience, has been the most powerful drug available for treatment of chronic and acute schizophrenics. For this reason it appeared to be particularly suitable for the present study.

Before we report our findings an attempt will be made to summarize what is known about the effect of the various somatic therapies on auditory hallucinations. The scarcity of such reports is indeed deplorable.

Dussik(1) found in insulin-treated patients that the auditory hallucinations would first become softer and more distant, then less obtrusive and less important, and finally they would disappear altogether. In his discussion of insulin-treated patients, Kalinowsky(2) states:

Delusions and hallucinations are usually the first to yield. It is important to note that improvement appears first in a reduction of the emotional charge behind the delusions and hallucinations: their dominance or obsessiveness is diminished. With the reduction of the emotional charge, the feeling of reality of the delusions and hallucinations is reduced. Many patients report that the hallucinations become fainter, the voices are less insistent or sound further away and indistinct.

In regard to psychosurgery, the statements found in the literature are rather conflicting. Stengel(3) reported that hallucinations were unchanged in 117 out of 154 cases. On the other hand, Freeman and Watts(4) found that the hallucinations

disappeared in 18 out of 19 cases. Kalinowsky(2) summarizes his own experiences as follows:

We have seen that during the immediate post-operative period, delusions and hallucinations disappear temporarily with more extensive operations such as standard lobotomies, and for an even shorter time or not at all after such relatively minor procedures as topectomy. When they presently reappear, however, they usually do not regain their earlier importance to the patient. He hardly talks about them spontaneously, and does not act on them. He loses interest in them progressively, and after several years they may disappear for good.

Kielholz(5) in his report on treatment with chlorpromazine, histamine and insulin, found that gradually the hallucinatory experiences disappeared from the foreground and could be influenced by reasoning with the patient. Sometimes the hallucinations stopped rather abruptly.

Feldman(6) studied a group of 119 patients treated with chlorpromazine and found 30.5% markedly improved, 27.5% moderately improved, and 21% slightly improved. Unfortunately, no information is given about the kind of improvement and the criteria for classifying a case into one of the 3 categories. In a subsequent study on trifluoperazine, Feldman(7) found "significant improvement" in 75% of his patients compared with 58% in chlorpromazine treatment.

Our study is based on 60 female schizophrenics in whom auditory hallucinations was a conspicuous symptom. They were treated with an average dosage of 40 mg. of trifluoperazine. The usual starting dose was 15 mg. daily, given orally in divided doses: the dosage was gradually increased according to the response noted. The lowest dosage given was 20 mg. daily; the highest, 80 mg. For the purpose of evaluating the effect of trifluoperazine we used the 4 main characteristics of hallucinations mentioned by E. Bleuler(8): intensity, distinctness, projection, and reality value. We added a fifth criterion: frequency of the hallucina-

¹ Chief of Female Service, Danvers State Hospital, Hathorne, Mass.

² Trifluoperazine was provided for this study as "Stelazine" by Smith, Kline and French Laboratories.

tory experiences. Duration of this study was 3 months. Patients were interviewed by the author in an informal way once or twice weekly during this time. Leading questions were carefully avoided. Frequently the patients would mention spontaneously the changes that they had noticed.

At the end of 3 months the auditory hallucinations had stopped completely in 39 out of 60 cases. In addition, improvement was noted in the attitudes and behavior of most of the patients. They became more friendly and cooperative and showed renewed interest in ward activities. Table 1 shows the changes observed in the patients' hallucinations.

DISCUSSION

Frequency was the first criterion that responded to treatment, and a reduction of frequency occurred in all patients. In 12 cases the change was noticeable within 24 hours of the start of treatment, and the end result was practically reached within the first 3 weeks. The 39 cases that showed complete arrest of auditory hallucinations did so before the fourth week of treatment, and about one third of them had been subject to very frequent hallucinations almost continuously for several months or even years. At the termination of the study 17 patients experienced their hallucinations only before going to sleep.

Intensity: Here again we saw a rapid decrease within the first week, and only 8 patients reported any changes after the first month. It seemed impractical to differentiate between moderately and greatly

diminished intensity. Voices that had not been overly loud were reduced to a whisper, very loud voices were reduced to a normal conversational tone and finally to a barely audible whisper.

Distinctness: The change occurred here somewhat later than in the previous two categories, but only 18 patients reported any change after the first month. In a typical case of the "moderately diminished" group the patient reported that the voices had become somewhat vague and unclear; only part of the words could be understood, but the general meaning was still clear. Three patients no longer referred to their "voices" but described their experiences as "vivid thoughts" or just "thoughts." One patient finally perceived only a confused incomprehensible murmur. These 4 cases were classified as "greatly diminished distinctness" since the distinctness of their hallucinations had previously been very high. Of the 39 patients who no longer had any auditory hallucinations, 21 had previously been subject to very distinct hallucinatory experiences.

Reality Value: Before treatment, 20 patients had occasionally expressed doubt about the reality of their hallucinations, and 40 were fully convinced that they were real. All of the former showed complete arrest of hallucinations at the end of the study. Of the latter, only 3 patients remained fully convinced of the reality, 5 expressed doubt, 13 conceded that they were probably not real and called their experiences "imaginings," and 19 were no longer hallucinated.

Projection: In 4 of the patients who

TABLE 1
EFFECT OF TRIFLUOPERAZINE ON AUDITORY HALLUCINATIONS

	Halluc. stopped	Greatly diminished	Moderately diminished	Not diminished	Increased
Frequency	39	17	4	0	0
Intensity	39	19		2	0
Distinctness	39	4	7	10	0
Reality Value	39	13	5	3	0
	Halluc. stopped	Change from within to without	Change from without to within	Other changes	No change
Projection	39	1	2	6	12

were completely relieved from auditory hallucinations, we saw a change from without to within (usually inside the head or ear) before the hallucinations were finally arrested. Thirty-five patients did not notice or report any change of projection before total stop. Two reported a change from without to within but continued to be hallucinated at the end of the study.

One patient who had formerly localized the voice within her stomach told us 3 weeks after being placed on trifluoperazine that the voice was now coming out of the wall where she thought a radio-telephone was hidden. Six patients showed other changes: two who had been subject to very unpleasant and disturbing auditory hallucinations which they thought originated only a few inches away from their ears reported now that the voices came out of the next room, or the room above. Four patients who continued to hear voices throughout the study, told us that the voices were now coming from a very great distance; they were unable to say from which direction, but the voices were fairly loud and very clear.

According to Gruhle(9), a patient who localizes the voice in his head commits an act of judgment rather than experiencing an immediate topical perception. In our study no patient had localized the voice in her head before treatment, and only 6 did so during the course of trifluoperazine therapy, in spite of the fact that the great majority of our patients developed good insight and judgment during treatment.

E. Bleuler's statement(8) that the 4 main characteristics of hallucinations are entirely independent of each other was confirmed by our observations. Some patients had infrequent, barely audible and very indistinct hallucinations that were characterized by high reality value. There were very intense and distinct hallucinations with little or no reality value, and there were intense but indistinct hallucinations. While trifluoperazine did affect all of these characteristics in the overwhelming majority of our patients, the various characteristics were affected not always at the same time or to the same degree. Distinctness and projection appeared to be

the characteristics that were less frequently influenced than the others.

In comparing our results with those obtained in insulin coma therapy, we find many similarities. Surprising, however, is the lack of uniformity in response, and the large number of rather abrupt arrests of hallucinations without the easier to understand step-by-step reduction usually seen in insulin patients.

In an earlier paper(10) we referred to the significance of the extrapyramidal syndrome in neuroleptic therapy. Although these extrapyramidal symptoms frequently accompany therapy with trifluoperazine, they respond well to antiparkinsonian agents and do not prevent a favorable therapeutic response. At first glance, it seems unlikely that trifluoperazine's marked effect on auditory hallucinations is in any way related to its very pronounced effect on the extrapyramidal system. But at least one possible connection might be considered. Hallucinations are "false sense perceptions" and they do have certain qualities in common with real sense perceptions. Schilder's experiments(11) have shown us that they react, for example, to vestibular irritation in a way similar to perceptions. A few years ago, Jacob(12) published a monograph on altered perception in extrapyramidal disorders. He found frequent and typical disturbances of perception in his patients, and this is not at all surprising if one remembers (as the Gestalt psychologists have stressed again and again) that the perceptive process is a continuous interplay between motor and sensory factors.

Movement and perception cannot be separated. Movement is a necessary condition for perception. It is conceivable that trifluoperazine's striking effect on auditory hallucinations has something to do with the motor component of the disturbed perceptive process in these patients.

CURRENT PROBLEMS IN DYNAMIC PSYCHOTHERAPY IN ITS RELATIONSHIP TO PSYCHOANALYSIS¹

FRANZ ALEXANDER, M.D.²

The current trend toward applying psychodynamic reasoning to psychotherapy which in certain respects differs from the standardized form of psychoanalytic treatment is one of the most significant developments in psychiatry. Freud foresaw this development in his often quoted statement in which he compared psychoanalysis with gold and other psychotherapeutic procedures with its alloys. This unmistakably implies a value judgment, and permits certain reflections concerning the underlying reasoning. It obviously stems from Freud's conviction that the aims of psychoanalytic treatment and research run parallel. Psychoanalysis aims at the genetic understanding of the patient's complaints. According to Freud, insight into these origins is the primary therapeutic agent. Etiological research and psychoanalysis accordingly have the same objective: to understand the origins of a disease. Referring to psychotherapy, Freud obviously meant that the latter was not an attempt to penetrate into the early determinants of the patient's current complaints. It tries to alleviate them with procedures which are not etiologically oriented, at least not to the same degree as classical analysis. In it the pure gold of etiological understanding is mixed with less valuable practical objectives.

There is growing doubt among many experienced analysts concerning such a complete parallelism between the aims of genetic research and psychoanalytic therapy. Freud's parallelity statement is only approximately true. It was, however, a most fortunate position at the time when Freud pronounced it. It was a logical outcome of his conviction that in order to cure a disease one must understand its causes. Therefore, his first interest was in understanding the nature and the origins

of neurotic illness. This was the first indispensable step towards attempting to cure it. To this basic conviction of Freud we owe the development of his personality theory, of psychodynamics as a basic science of psychiatry and of all disciplines which are concerned with man as a social being. It replaced the hit and miss type of psychotherapy, which lacked any sound theoretical foundation and an etiologically oriented treatment.

It was indeed fortunate that for a long time the theoretical interest in etiology outweighed therapeutic ambitions. Freud, according to his own testimony, never was a therapeutic enthusiast. His overwhelming curiosity to understand the genetic background of his patient's problems is clearly reflected in his earliest technical recommendations, which stressed the significance of insight.

The first serious challenge to the thesis that the patient's own genetic understanding of his neurosis is the primary therapeutic factor occurred when the transference phenomenon was discovered. Freud then proclaimed that the patient, in order to be cured must not only understand his neurotic past, but re-experience it in relation to the therapist. Emotional re-living of the past, in addition to insight, now took an important place in the theory of the therapeutic process.

The relation of the emotional re-living of the past to intellectual insight is still an open question. Freud never changed his view that remembering of repressed traumatic situations is the ultimate goal. Only remembering those early events in which the neurotic patterns originated enables the patient to terminate their compulsive repetition in the transference and in his life. Ferenczi and Rank challenged this theory and maintained that re-experiencing during treatment of previous dynamic patterns alone without remembering the original events in which they originated, permits the patient to recognize their past determined nature and exchange them

¹ Read at the 115th annual meeting of The American Psychiatric Association, Philadelphia, Pa., April 27-May 1, 1959.

² Mt. Sinai Hosp., 9270 Beverly Blvd., Los Angeles 48, Calif.

with attitudes appropriate to the present. This view was rejected by most analysts as well as by Freud, although it was never subjected to a detached empirical evaluation. This emphasis on emotional experience by no means questioned the postulate that the therapist must understand the genetic background at least intuitively, but preferably consciously, in order to conduct the treatment effectively.

In a series of writings I revived this old unsettled issue by pointing out that the repeating of the old interpersonal reaction patterns during treatment constitutes a corrective experience, because they are repeated towards the therapist who does not behave in the same way as those original objects behaved towards whom the patient's original pattern were directed (1, 2, 3, 4). I emphasized, as did other psychoanalysts, that neurotic reactions do not develop in a vacuum, but are the child's unsuccessful adaptive reactions to environmental influences. The repetition of old patterns in a new setting, to which they do not fit, serves as a challenge to the patient's ego for readjustment, to exchange old patterns with new appropriate ones. One of the ego's basic functions is the constant readjustment of behavior to the everchanging external and internal situations. The neurotic ego lost this flexibility and remains fixated or easily reverts to old modes of feeling, thinking and acting. The transference situation is a unique experience, inasmuch as the therapist's behavior is different from that of the original significant persons in the patient's past life, but it also differs from the behavior of other persons who react to the patient's fixed behavior patterns and mostly reinforce them. The therapist's un-involvement mobilizes the ego's basic function to attempt a new appropriate adjustment.

It is obvious that from this perspective the cognitive act, namely the intellectual recognition of the difference between past and present is secondary to the actual experiencing this difference in interacting with the therapist. In this view the emphasis shifts from insight to experience, although the role of insight as a secondary but often powerful consolidating factor is by no means denied. This emphasis on

emotional experience has been earlier made by others, particularly Aichorn in his treatment of delinquent youth. The therapist's permissive, yet uninvolved, behavior is perceived by the patient as a quite novel experience, and induces him to change his own responses. The old controversy between Plato's and Aristotle's learning theory—learning through logical insight versus learning through practice—is revived in this current argument. It appears to me that we deal here not with a question to which the answer is either/or. Both principles—experience and insight—are operative in every form of learning, also in the specific form of re-education we call psychoanalysis, and, if I may add, also in dynamic psychotherapy. If some analysts choose to call this new emphasis on emotional experience a dilution of the true concepts of the classical theory, I can only answer them that the phenomena in nature seldom can be understood from one single principle. Even the phenomenon of radiation could not be adequately described by the undulatory theory alone and required the revival of the older corpuscular theory. Certain aspects of radiation require the undulatory, other aspects of it the corpuscular theory. The emphasis on the emotional events during treatment may dilute the purity of the single-minded emphasis on insight, but only the two together do adequately describe the actual therapeutic process.

Here is the point where the aims of etiological research and treatment begin to diverge. As long as insight into the origins of the disease were considered as the principle therapeutic factor, the aim of genetic research and psychoanalytic treatment indeed coincided. The stress on emotional experience alters the absolute validity of this contention. It is quite possible that by focussing attention upon the emotional interaction between therapist and patient, the cognitive reconstruction of past events will lose its primary significance, although I believe that in many treatments this will always remain a potent factor. At present it would appear to me that intellectual insight mostly follows rather than precedes corrective emotional experiences. It is made possible by the latter. Bluntly stated, profound therapeutic results may

arise from merely corrective experiences even if they are not followed by the revival of repressed memories. Cognitive reconstructions alone never have penetrating therapeutic effect. The appearance of repressed memories is the sign rather than the cause of an emotional change which has already taken place.

This is the crucial point where dynamic psychotherapy and classical psychoanalysis merge. The creation of an appropriate interpersonal climate which fosters that type of emotional experiences which induce the ego to replace old patterns with new ones is the predominant factor in all dynamic psychotherapies, including psychoanalysis. Our current studies in the Mt. Sinai Hospital, in which we observe the therapeutic interaction between therapist and patient, both in psychoanalysis and psychotherapy, convinced our research team that the cognitive and emotional events can only be artificially separated. Moreover, it is becoming clear to us that the influence of the individuality of the therapist is a crucial, although yet almost completely unexplored, factor.

According to the blank screen model of the classical theory, the analyst functions incognito as a neutral intellect who masters the psychoanalytic theory. This concept is being amended by growing consideration paid to the analyst's countertransference reactions as a significant factor in the therapeutic process. A further crucial question is how much, apart from his specific countertransference reactions, the therapist as a distinct individual enters into the therapeutic process. Or, in other words, would the course of the treatment be the same if the patient were treated by a different analyst with the same theoretical orientation and practical experience, but having a different personality—for example, had the patient been treated by a woman instead of by a man, by a younger man instead of an older man, by a reserved rather than an outgoing personality. How are the specific personality features of the therapist, including his own value systems, perceived by the patient even if the analyst tries to keep his incognito, and how does all this influence, if at all, the transference and the whole course of the treatment?

These and many other vital questions are today unanswered. What seems to be certain is that the patient does not perceive the analyst only as an abstract intellect, but as a distinct person. This fact must be included in an adequate theory of the therapeutic process.

It also appears to be certain that the emotional and the cognitive factors are organically connected. This fundamental fact makes the efforts to divide psychotherapeutic procedures, including psychoanalysis, into rigid categories, both artificial and futile. Knight lucidly expressed this view in 1949 in emphasizing that fundamentally there is only one psychotherapy which "must rest on a basic science of dynamic psychotherapy" (5). The patient's condition and the spontaneous course of the therapeutic process, and not our own preconceived artificial categories, prescribe our activities and interventions. Even emotional support alone may introduce spontaneous insight by decreasing anxiety which interferes with insight. In fact, I suspect that the supportive effect of the psychoanalytic process has been not sufficiently recognized as one of the main factors favoring both insight and the emergence of new emotional patterns. Quite rapid puzzling transference cures may find their explanation precisely in this circumstance: the emotional support which the patient derives from the treatment situation may restore the ego's temporarily impaired integrative capacity, and thus introduce a spontaneous healing process.

This view, if it is valid, unavoidably must have an effect upon our training practices. Knight's tersely stated principle did not yet affect our educational policies sufficiently. Psychoanalysis and dynamic psychotherapy can only be taught and practiced together as one comprehensive field. To implement this principle is extremely difficult at present because of our traditional customs and status considerations, and above all because of the current trend in all aspects of our civilization towards organization and standardization.

Our field is too young to be allowed to be frozen prematurely by this organizational fervor, which demands clear cut,

standardized, but often quite artificial, professional categories. In spite of this, because of its practical effectiveness and theoretical soundness, dynamic psychotherapy is in the process of introducing a new fresh point of view in psychiatry, which is not weighted down by a heavy load of traditional beliefs and practices. Gradually it will transform not only the education of psychiatrists, but psychoanalytical training itself.

SENSORY DEPRIVATION AND SCHIZOPHRENIA: SOME CLINICAL AND THEORETICAL SIMILARITIES¹

NORMAN ROSENZWEIG, M.D.²

During the recent past, the effects of sensory deprivation have been extensively reported in the literature. The effects of sensory deprivation have been reported in the human, animal, and plant kingdoms. The effects of sensory deprivation have been reported in the human, animal, and plant kingdoms. The effects of sensory deprivation have been reported in the human, animal, and plant kingdoms. The effects of sensory deprivation have been reported in the human, animal, and plant kingdoms.

It is not the purpose of this paper to discuss the mechanisms responsible for these effects. However, these effects have been reported in the human, animal, and plant kingdoms. The effects of sensory deprivation have been reported in the human, animal, and plant kingdoms. The effects of sensory deprivation have been reported in the human, animal, and plant kingdoms. The effects of sensory deprivation have been reported in the human, animal, and plant kingdoms.

I should like to present a brief reconstruction of the sensory deprivation question. It was prompted by certain clinical observations. It derives, as the title of this paper indicates, from the resemblance in clinical picture between the effects of sensory deprivation and the schizophrenic syndrome.

First allow me to tell you about two types of case which have come to my attention. The first is of a kind that we saw not too infrequently in the Air Force. A young Air Policeman was sent on guard duty alone, at night, on an isolated post.

The young man, often not too bright but otherwise without prior difficulties, would become apprehensive, because he would hear voices in the darkness around him, and become progressively, usually, more paranoid. He would be found the next morning in a withdrawn, perplexed state, and brought in for psychiatric examination. Characteristically we would find a schizophrenic picture with confusion in thinking, affective instability, suggestibility, and other features. He would have delusions and paranoid ideas. Usually the clinical picture cleared up within a few days, without apparent sequelae. I have been told that because of such difficulties, airmen are no longer sent out alone on solitary guard duty.)

The other type of case is illustrated by a 38-year-old woman with retinal detachment being prepared for surgery, on whom psychiatric consultation was requested because of the development of the delusion that her medication was poisoned. She was married, described as "high-strung," but otherwise without prior psychiatric difficulty. Family history was also completely negative for mental illness.

When seen she was one of 5 patients remaining on a ward that had been largely evacuated for redecorating. The patient's bed was some distance from the other remaining patients, and was surrounded by screens. Both eyes were covered with bandages. She was noted to be quite restless, her hands and face in constant movement. Her thought processes were confused and rambling. Her voice was whining and childish. She complained that her medication was poisoned, and that she was being smothered. She told of seeing a "funny little man" like a cartoon, and said she was unable to tell whether she had been dreaming or awake at the time.

The patient was operated the following day, after which only one eye was bandaged and she was brought into closer contact with other patients and staff. The psychotic aspects cleared almost at once and the patient was discharged a week

³From the Department of Psychiatry, University of Michigan Medical School, Ann Arbor, Mich.

easy, free from mental abnormality. Examples are of course not unique. If psychiatrists have seen similar cases have read about them. They are of great interest, however, because both these conditions involve the development of a psychotic, schizophrenic-like condition when the subject is in the conditions of a restricted sensory environment.

It will be recalled that long before work began on experimental sensory isolation there were many reports of such experiences. Hallucinatory experiences were reported by explorers(14), but even more interesting are the more complete reports of such men as Admiral Byrd and Bombard(3). Byrd spent 6 months in the Antarctic; Bombard crossed the Atlantic alone on a raft. Yet the experience of both was remarkably similar. Both drew "deeply into themselves for emotional sustenance." Both had difficulty maintaining organized thought, and in maintaining control over himself and his environment; and each developed compulsive-type defenses such as structuring the daily routine, adherence to a strict schedule, doing mathematical problems, etc. Both experienced difficulty in testing reality, and doubted the validity of their own thought. Both tried to force their thinking toward pleasant associations from the past and away from the anxiety-producing aspects of their current situation, in order to ward off depression.

General Dean(4), a prisoner of the Chinese Communists, had almost identical experiences. He became depressed, even attempted suicide in his isolation. He, too, tried to maintain control over his own thinking by using compulsive defenses such as doing algebraic problems in his head, and calisthenics (even when this was reduced to crossing and uncrossing his fingers). He, too, doubted the validity of his own thoughts, and had difficulty in testing reality. He could not maintain organized thought, and drew into himself.

Other such prisoners had similar problems. There was inability to demarcate truth and fiction, to determine the validity of experience. Impairment of organized thinking, mental dullness, depression, and

other psychotic symptoms, including hallucinations(14). When Heston and his co-workers in Hebb's laboratory at McGill set up the sensory deprivation capsule, they found that the subject, in experiencing "brainwashing" in early phases of the experiment, had only minor and temporary effects on perception and thought, but that as time went on, the subject began to show more serious, well-rounded psychotic symptoms(15).

Nearly all subjects reported that the most striking thing about their experience was that they were unable to think clearly about anything far and for the future, and that their thought processes seemed to be affected in other ways(16). They were unable to concentrate, and showed impairment on tests of mental performance. Their inability to maintain organized and directed thought activity was accentuated by changes in thought content in the form of autistic fantasy. Ingressive behavior was also seen with Penikese prisoners. Inability to handle affective reactions, reality testing was impaired, and distortions of body image and hallucinations were reported(8, 2).

Felt(1) describes regression from secondary to primary process thought activity. There was a loss of directed thought and a shift to autistic, highly personal and emotionally "charged" reveries and fantasies, sometimes followed by projection of visual imagery(9).

Selmon and his co-workers at Harvard, using the tank type respirator, have found disturbances of abstract thinking, regressive behavior, autistic fantasy and impairment of reality testing. They, too, have seen bizarre disorganization with delusions and hallucinations(11, 10).

Freedman, Grunebaum and Greenblatt report difficulty in thinking coherently and in concentration, changes in body image, visual and auditory illusions and hallucinations, and unreal or paranoid fears, all within a framework of autistic withdrawal(5).

Goldberger and Holt report both Rorschach and behavioral phenomena indicative of regression from secondary to primary process activity. Their subjects demonstrated decreased efficiency and continu-

ity of thought severe affective disturbances, increase in vividness and frequency of imagery, disturbances in time sense, depersonalization, and body image disturbances (6, 7).

One cannot help noting that throughout these reports—clinical, autobiographical, experimental—there appear again and again Bleuler's cardinal symptoms of schizophrenia: disturbance of associations, disharmony of affect, autism, ambivalence. We see disruption of secondary thought processes, regression to the primary process, impairment of reality testing, and in addition, such accessory symptoms as distortion of body image, depersonalization, delusions, hallucinations. As a model psychosis, the sensory deprivation experiment much more closely resembles schizophrenia than do the experiments with LSD or mescaline.

It seemed quite logical therefore, to attempt an interpretation of the sensory deprivation effects within the framework of a theoretical model which we had developed from a consideration of schizophrenia (12). This model, which attempts to correlate psychological and physiological findings, is described more fully elsewhere (13, 12), and cannot be detailed here. A brief outline, however, may serve to sketch in a few of the pertinent concepts.

The theory holds that normal mental activity is dependent upon the appropriate interaction of two functional systems. The more primitive *affect system*, functionally reminiscent of Freud's primary process, is represented anatomically in the rhinencephalon and the subcortical structures with which it connects. This system receives messages relative to ongoing bodily processes. A homeostatic shift will cause the affect system to scan the perceptual stream for those cues which have come to be associated with return of equilibrium. The significance of a percept is thus determined by the relationship of its representation to the internal state, i.e. to potential gratification or potential danger. The conscious counterpart of this relationship is the affect. While the affect system serves the vital function of establishing the relevance of experience for life, it is limited to qualitative discriminations and is autistic in orientation.

The phylogenetically more recent *abstract system* is represented in the neocortex, and is roughly analogous to Freud's secondary process. It is this system which receives and correlates stimuli from the various sense modalities, and by means of such consensual validation of experience serves to test reality. By elaborating and abstracting perceptual data, it functions normally to define experience sharply, makes available to the affect system a broader base for decision making, and enables the organism to meet the demands made upon it by the environment.

Ordinarily, the sensory input, after initial correlation and elaboration by the abstract system, is communicated to the affect system, which seeks to establish the relevance thereof for current and prior needs and for ongoing processes. This information is then fed back to the abstract system, where it serves as the basis for further elaboration, and so on. This back and forth communication between the two systems permits a sequence of meaningful associations which is at once reality oriented and useful in problem solving.

Within this framework, then, we have postulated that the symptoms of schizophrenia result from an internal derangement which interferes with the communication between the systems (12), thereby preventing the reliable determination of the significance of perceptions. This breakdown is seen to result in disruption of the stream of associations and consequent dominance of behavior by the now unchecked and uncorrected autistically oriented affect system, i.e. regression. The critical factor in schizophrenia is thus assumed to be the inability to establish the relevance of sensory experience for ongoing processes.

The situation in sensory deprivation is at once seen to be analogous. Here the interference is external, but the effect is the same. By limitation, depatterning or redundancy the stimuli are deprived of meaningfulness for the subject. When perceived, their relevance for meeting current needs cannot be established; the consequences of this situation are seen in the breakdown of secondary process activity and impairment of reality testing. Our approach suggests that it is the restriction of

meaning rather than the physical limitation of stimuli *per se*, which is primarily responsible for the effects of sensory isolation.

If we are correct, then, the importance of limiting sensory input lies in the limitation of useful information; and even considerable input, if it were deprived of relevance, should lead to a schizophrenic-like state. We suggest that the common denominator in schizophrenia and sensory isolation is *relevance deprivation*, which may be produced artificially by a number of other methods of perceptual manipulation, such as perceptual distortion and sensory overload. These are propositions which are susceptible of experimental investigation; such investigations are currently being developed in our laboratories.

CONCLUSION

It would seem, in fact, that we now have an experimental model of the schizophrenic syndrome superior to the "model psychoses" induced with mescaline or LSD. Not only will perceptual interference reproduce more closely the primary symptoms of schizophrenia, but these disturbances are caused entirely by external manipulation, without the confusion of a toxic psychosis. While of course we cannot assume that approaches such as these will give us valid answers to all our questions, I believe we have here an important instrument to help us bridge the gap between the laboratory and the clinic.

A STANDARDISED TECHNIQUE FOR MODIFIED ELECTROSHOCK THERAPY USING SUCCINYLCHOLINE CHLORIDE

HARRY K. ROSE, L.R.C.P.¹ & S. (Ed.), D.P.M.

INTRODUCTION

In 1941 A. E. Bennett reported on the use of curare as a muscle relaxant capable of preventing fractures and dislocations during convulsion therapy.

More recently other workers, Moss *et al.*, (1953), Impastato and Berg (1956), Jerome Rietman *et al.*, (1956), have described the use of other muscle relaxants and have emphasized the need for an accompanying short-acting anaesthetic (thiopentone). Increasing in popularity is succinylcholine chloride (SCC) which is commonly felt to be the most effective and safest relaxant of those in current use.

The established practice, in this country, is for the SCC to be given with an accompanying anaesthetic, either mixed together in one syringe or separately. Sargent and Slater (1956) state "Scoline (SCC) administration must always be preceded by unconsciousness produced by pentothal, as the feeling of progressive paralysis which would otherwise be felt is terrifying."

It is for this reason that anaesthetics have continued to be used and these authors also make the point "But it is certain that if muscle relaxants came into general use and are handled by psychiatrists unversed in anaesthetic techniques, the death rate from ECT will increase alarmingly." This statement is supported by Maclay's (1953) figures showing that 45% of deaths associated with ECT were in cases when a relaxant was used, although they could only have been a very minor proportion of all cases treated.

The risk of modified treatment must surely be considerably lessened if a simple technique were involved whereby an accompanying anaesthetic is not required. The implication of Maclay's figures may be that thiopentone relaxant technique in the hands of psychiatrists with little knowledge of anaesthetic procedures is dangerous.

We should not be too ready to incriminate the muscle relaxant drugs without sufficient evidence.

A relaxant technique without an anaesthetic means a safer, easier and quicker administration which is probably more effective. There is some evidence that a longer course of treatment is needed when ECT and relaxant and anaesthetic is given than when ECT is not accompanied by an anaesthetic. Several workers have reported on the use of relaxants without anaesthetics. There have been important differences of technique which may possibly have led to some confusion and resulted in no single method being generally adopted. Murray (1953) uses small doses of SCC (20 mg.) and times the shock at 10 seconds after the onset of facial twitching. Impastato and Gabriel (1957) followed Murray's timing technique but realised that the SCC did not develop its full effect when the shock was given. To reduce the severity of the convulsion they used a special machine (Reiter A.C. instrument Model Molac II) giving an initial high voltage shock to produce an amnesia 10 seconds after SCC injection and a further shock 20 seconds later to give a convulsion. Kelleher and Whiteley (1955) used SCC alone, comparing its action with SCC and thiopentone and suxethonium bromide alone. Using SCC alone the shock was timed at 10 seconds after the beginning of facial fasciculation. Mild anxiety in association with facial fasciculation was reported in one third of the patients. Using suxethonium alone they found that more than half of the patients experienced severe anxiety and suggested this was due to the shock-like onset and rapid spread of paralysis that took place with this drug. They concluded that SCC was the drug of choice and quoted Gillies and McNeil (1955)—one patient who recalled on several occasions a sensation of smothering following the injection of suxethonium bromide. Glover and Rosium (1954) using SCC alone required a team of 5 persons to hold the patient, the shock being given after the

¹ Assistant Psychiatrist, Warlingham Park Hospital, Surrey, Eng.

appearance of obvious facial fasciculation or respiratory embarrassment, or both.

The purpose of this article² is to standardise a simple technique for modified ECT using SCC without an anaesthetic, a technique which is safe and without undesirable side effects. This technique has been used by the writer for the past 4 years. No other doctor was required to be present. The experience covers more than 3,000 treatments, both inpatient and outpatient. There were no resultant fatalities.

TECHNIQUE

Method of Administration.—No food or drink is allowed for at least 2½ hours prior to treatment. Thirty minutes before treatment 1/100th gr. of atropine sulphate is injected subcutaneously. In cases of urgency it may be injected intravenously immediately before or with the scoline; but this has not been found quite so effective.

Position of Patient.—The patient lies comfortably on a couch, bed or stretcher on top of which is placed a firm mattress. A pillow is placed under the head. If the mattress tends to sag another pillow is placed under the small of the back but no active attempt at hyperextension of the spine is made. No restraint is used. The patient is merely told that he is going to receive an injection which will relax all his muscles and is reassured that there is nothing to worry about.

Dosage of Succinylcholine chloride.—The dose of SCC to be given is estimated by the weight and muscularity of the patient. This is not the only consideration, however, for muscular response is also dependent on pseudocholine esterase titre. The effect of this is only seen after the first injection, when patients having a low titre may be found to have more complete relaxation and prolonged apnoea than expected in the normal. Slight adjustment in dosage may then be made.

Dosage.—Average dose for men 30 mg., for women 25 mg.; 5 mg. less is given to

those over 60 years old. Where there is a history of chronic chest disease, or if chest deformity is present, dosage is lowered to 20 mg. for men and 15 mg. for women.

These doses have been found sufficient for all routine cases where there is no special indication for modification with muscle relaxants. If however, there is a special risk of fracture or other injury the dose is increased by 5-20 mg. according to the need for more complete relaxation. The second and following doses may be adjusted according to the initial response. In the routine case, partial muscular relaxation is all that is required and where relaxation and/or accompanying apnoea are too severe, the dose is reduced by 5 mg.

Rate of injection of SCC.—A rapid injection is given (2-3 seconds) in order to bring on paralysis as quickly as possible. Slow injections tend to delay the onset of paralysis and increase the likelihood of untoward reactions.

Mouthpiece.—If the patient has teeth a gag is inserted into the mouth immediately following the SCC injection. The patient is asked to bite on it and the jaw is held with moderate firmness. The edentulous patient does not require a gag.

TIMING OF SHOCK TREATMENT

Success in avoiding untoward reactions, the principle one being a sensation of choking, depends on skilful timing. Immediately following the injection the patient is told to raise his other arm to a right angle and keep it there as long as possible. When the arm can no longer be held up and begins to fall to the side, the shock is given. This occurs at a variable time after the injection, usually between 5 and 15 seconds, occasionally being prolonged to 30 seconds. The disagreeable choking sensation appears after the relaxation of the arm and does not therefore trouble the patient. I have questioned many patients following a course of shock treatment using at different times SCC with and without pentothal. The last thing the patient who has SCC without pentothal remembers, is the injection of SCC. He usually believes that it was this injection which put him to sleep.

USE OF OXYGEN AND AIRWAY

During the convulsions an airway is

² I am indebted to Dr. F. H. Hare for his encouragement and advice. I should like to thank Dr. R. K. Freudenberg, Medical Superintendent of Netherne Hospital, Dr. T. P. Rees and Dr. S. A. MacKeith, past and present Medical Superintendents of Warlingham Park Hospital, for giving every facility for the carrying out of this work.

slipped over the gag, the latter being removed. In the edentulous patient the airway is inserted at this point. Oxygen is given by a positive pressure rebreathing bag when the fit shows signs of terminating. However, with such small doses of SCC as described, the patient often resumes spontaneous breathing immediately following or a few seconds after the convulsion without insufflation of the lungs.

When slight anoxia is considered to be dangerous in a particular case, *e.g.*, where heart disease is present, oxygen is administered immediately after the giving of the shock.

RATE OF RECOVERY

This occurs as rapidly as in unmodified shock treatment. This is of particular importance in the outpatient clinic where a speedy recovery without the sleepiness and confusion associated with thiopentone is of considerable advantage. Thus, the patient is allowed to leave the department safely one hour later following a very short period in the recovery room (15-25 minutes). Relatives or friends who accompany the patients are relieved of a tedious wait and are most grateful for this.

COMPLICATIONS OF TREATMENT

The series has been remarkably free from complications and untoward effects. Prolonged apnoea of 3-5 minutes occurred in 3 very old persons. These patients had low tidal volumes and a more prolonged period of apnoea was expected. Manual respiration was found to be more effective than the positive pressure rebreathing bag in aiding resuscitation. One patient developed paroxysmal tachycardia on termination of the fit. This lasted 15 minutes and was brought to an end by carotid sinus pressure.

On two occasions the shock was not given due to a fault in the machine and once the headpiece fell off the table and the movable electrodes which had broken off were not able to be reassembled in time to give the shock. These mishaps resulted in the patients experiencing the disagreeable choking sensation due to SCC. They were however able to continue treatment after reassurance. The latter mishap can-

not now occur as the electrodes are incorporated into the headpiece.

There were no fractures or injuries resulting from treatment.

Lastly, it is important to have an impeccable intravenous technique so that the patient does not become alarmed at the doctor searching and probing for a vein. When complete relaxation is necessary, one must make certain that the total dose of SCC is given into the vein.

DISCUSSION

DIFFERENCES OF TECHNIQUE

1. The essential difference in the technique outlined from those of other writers, Murray(7), Kelleher and Whiteley(9) and Glover and Rosium(11), is in the timing of the shock. The shock is given when the patient's arm begins to fall to the side and not at a time related to the onset of facial twitchings. Kelleher and Whiteley(9), who described mild anxiety in one-third of their patients may have gained this impression from the facial fasciculation and signs of restlessness present. These are not necessarily signs of anxiety.

The retrograde amnesia produced by the shock may account for the lack of complaint of anxiety by some patients, but it is by no means certain that allowing for this these patients have experienced any anxiety.

2. No restraints are used other than the nurse holding the jaw with moderate firmness.

3. Each case must be considered on its own merits when dosage is calculated, *e.g.*, degree of modification required, age, weight and muscularity of patient and the presence of coincident chest or heart disease.

RELAXANT V. RELAXANT AND THIOPENTONE

Fear of the terrifying anxiety said to be produced in the patient following SCC has been the main reason for relaxant techniques unaccompanied by thiopentone not being adopted. Recognised authorities in British psychiatry, *e.g.*, Sargant and Slater (5) have stressed the necessity for an accompanying anaesthetic emphasising the anxiety which would be aroused if this were not given. Experience has now shown

that these fears are groundless. There is a possible disadvantage in using a relaxant alone in that relaxation is not complete but in practice this does not matter because partial relaxation is adequate for nearly all cases. The patient may however be more restless in the recovery phase.

Advantages of relaxant given alone include:

1. Easier, quicker and safer administration.
2. Fewer attendants required. One doctor and one nurse, is minimum requirement.
3. Rapid recovery.
4. No anaesthetic complications.

There is much to be said for giving a relaxant drug with every shock treatment. In some clinics this is routine practice. These are usually clinics where the total number of treatments per session is small, and an anaesthetist is always available. Some authorities require two doctors to be present when ECT is given; others stipulate that an anaesthetist must always be present. The present trend is to take ECT out of the hands of the psychiatrist transferring it to the presumed safer control of the anaesthetist.

However, the great majority of treatments today are administered in the mental hospitals where facilities are not available for anaesthetists to be present when ECT is given. Treatments would be considerably restricted and indeed urgent treatments would not be easily administered if anaesthetists were required in all cases. Another consideration, and not the least important, is the legal position of the psychiatrist working alone, who is unfortunate enough to have a death or injury follow treatment. His position might indeed be hazardous if it became established practice

for an anaesthetist to be present during modified convulsive therapy.

The present trend is a retrograde one. It is uneconomic and merely increases the difficulties encountered in the treatment of patients. The writer hopes that the procedure outlined may yet become the established practice in this country.

SUMMARY

A standardised technique for modified ECT using succinylcholine chloride without an anaesthetic is described in detail. Differences from previous techniques are explained. The advantages of a safer, easier and quicker administration of ECT are stressed.

CROSS TRANSFUSION IN SCHIZOPHRENIA

GEORGE NICKLIN, M.D.,¹ WILLIAM SACKS, Ph.D., HANS WEHRHEIM, M.D.,
GEORGE SIMPSON, M.D., JOHN SAUNDERS, M.D., AND NATHAN KLINE, M.D.²

In recent years, there has been much research as to whether or not a blood substance exists that is related to the schizophrenic reaction. Pfeffer and Pescor(1) performed exsanguination experiments with blood volume replacement in schizophrenic patients and were unable to demonstrate the presence of any toxin. This work has subsequently been repeated and validated. Winters and Flataker(2) reported changes in the motor performance of rats who were injected with schizophrenic serum. However, this finding could not be confirmed by Ghent and Freedman(5) who repeated the experiments. Heath, *et al.*(3) reported the presence of a blood substance which they had extracted by biochemical methods that produced a schizophrenic-like reaction in volunteers. These data have been difficult to confirm in other laboratories and have evoked a criticism by Siegel, *et al.*(4).

The cross-transfusion technique has been used many times in clinical studies of various diseases. It is not without risk, and a thorough study of the technique with a review of literature is reported by Salisbury, *et al.*(6). They also report in their own series a fatality. In a review of the literature on research in schizophrenia, no past study was found where a non-psychotic volunteer had been cross-transfused with an actively hallucinating patient. Accordingly, we undertook this study.³

MATERIAL AND METHOD

Our procedure was based on the simplest possible cross-transfusion method. It was performed with a 50 c.c. syringe used as a pump and No. 15 needles inserted into the antecubital veins of a patient and of a volunteer. The patient and volunteer were heparinized, and the volunteer received

an injection of Evans blue dye to determine the extent of blood exchanged. No other medication was given to the patient or volunteer for the 72 hours prior to the experiment, during the experiment, or during the several days after the experiment, with the exception of a course of Oxytetracycline administered prophylactically to the volunteer and the patient following the study.

The patient (F. F.) was a 39-year-old single, grocery clerk, of Mediterranean origin, who had been hospitalized for 19 years due to chronic schizophrenic reaction of the mixed type. He had hallucinations and delusions which were active. During the time before the experiment and during the experiment he was having auditory and visual hallucinations. He was also mildly paranoid at the beginning of the experiment, and had fluctuating bouts of catatonia. A physical examination and blood chemistry studies were within normal limits. Both the patient and volunteer were blood group "O," Rh- positive, and were compatible.

The volunteer (W. W.) was a 23-year-old married graduate student and conscientious objector. He was found to be a very gifted, creative individual of superior intelligence whose personality was within normal limits and without any evidence of psychotic response on his psychiatric and psychological examination. Blood chemistry studies were found to be within normal limits. Both the volunteer's and the patient's electroencephalograms were within normal limits. There was no evidence of any physical or neurological abnormality in either subject.

The procedure was carried out in a hospital operating room with surgical and medical supervision. Both the patient and the volunteer were given an initial control-run to make sure that neither would respond to the stimuli of the experiment. It was also planned that if any response should occur in the actual cross-transfusion a follow-up control study would be done.

² Director of Research, Rockland State Hospital, Orangeburg, N. Y., where this experiment was performed.

³ We are indebted to S. B. Wortis, M.D. whose suggestions made this experiment possible.

RESULT

During a period of 6 hours, a total of 6,800 c.c. of blood was interchanged; that is, 3,400 c.c. was transfused from the patient to the volunteer and 3,400 c.c. from the volunteer to the patient. The Evans blue dye suggested that a minimum of 31% mixing of the two blood volumes occurred during this period. During the first 21 minutes of the experiment (Table 1) 1,000

TABLE 1

275	6 L.
362	6.8 L.

c.c. of blood was interchanged; that is, 500 c.c. being sent in each direction. During the first 45 minutes of the experiment 800 c.c. of blood were interchanged in each direction. The procedure was somewhat prolonged due to the need to flush the apparatus with heparin in saline periodically, and due to occasional clots.

Throughout the experiment, no apparent clinical changes occurred in the patient or the volunteer. The patient continued to have visual and auditory hallucinations. The volunteer showed no signs of hallucinations, no signs of catatonia, no signs of delusions, no ideas of reference, or other psychotic symptoms. About 4 hours after the cross-transfusion had been discontinued, the patient became more catatonic than he had been previously, and more paranoid. He continued to have auditory and visual hallucinations. This period of increased catatonia and paranoia in the patient lasted for 24 hours following the completion of the experiment. The volunteer showed no signs of any clinical change, psychiatrically. Thirty-six hours after the experiment both the patient and the volunteer showed a febrile response with the presence of ronchi and a few rales in the lungs of both. They were maintained following the experiment on a pro-

phylactic dose of Oxytetracycline and the febrile response in both disappeared within 2 days after the onset, and the Oxytetracycline was discontinued after 5 days of treatment. Follow-up studies of the patient showed a reversion to his previous fluctuating catatonic state and a decrease in his paranoia following the first 24-hour period after the experiment. However, he continued to hallucinate. His hallucinations have continued up to 5 months after the experiment. At the end of 6 months after the experiment when the patient was examined clinically he was not hallucinating although he was having occasional bouts of catatonia and did have ideas of reference and some paranoid ideas.

Psychological follow-up studies on the volunteer showed that he had markedly improved in his interpersonal relationships during and after the period of the experiment. There is apparently no reason to believe that the improvement was related to the exchange of blood. The apparent improvement was believed related to the enhancement of self-esteem which occurred in the volunteer, coincidental with the experiment. Also, during the period of the experiment, shortly before the actual cross-transfusion, the volunteer was married, and apparently his heterosexual and interpersonal adjustment improved markedly at that time.

COMMENTS

From the findings of this experiment, one can conclude that cross-transfusion of moderate quantities of blood in a relatively short time has no apparent ill-effects on a volunteer, when the cross-transfusion is between him and an actively hallucinating schizophrenic patient. Indeed, it would seem that the patient was temporarily worse following the experiment, and that the volunteer was improved by the study. While this raises some question as to whether or not there is a toxic blood substance that would cause a psychotic response in a volunteer, it also raises a question as to whether or not a normal blood substance was supplied to the patient in larger quantities than he had been accustomed to, and that his body converted it into a toxin which produced a more

profound psychotic response than he usually had, or if his change was a simple stress response. While this study does answer the immediate question as to whether or not ill-effects will occur to a volunteer from such an experiment, it does not definitely answer whether or not there is a blood toxin. It would suggest that it is probably psychiatrically safe for a larger quantity of blood than was used here to be exchanged in a shorter period of time between a non-psychotic volunteer and a schizophrenic patient.

SUMMARY

In this study of cross-transfusion in schizophrenia no clinically significant changes occurred in the non-psychotic volunteer, during or after the cross-trans-

fusion. The patient became psychiatrically more ill during the 24 hours immediately following the cross-transfusion.

AKATHISIA: THE SYNDROME OF MOTOR RESTLESSNESS

JAMES R. HODGE, M.D.¹

Akathisia is "a name given by Lad Haszkovec to a form of rhythmic chorea in which the patient is unable to remain seated" (1). Freyhan (2) quotes Kinnier Wilson's description of it in his chapters on encephalitic and idiopathic Parkinsonism as follows:

Not a few subjects complain paradoxically that they cannot "sit still" or do so only "with an effort"; they must get up, or move about, or shift the position of their limbs, inaction having become unbearable.

Freyhan (2) then gives his own excellent description of this condition:

If akathisia is mild, patients complain of a feeling of inner unrest, of pulling or drawing sensations in the extremities but chiefly in the legs. Once akathisia is fully developed, patients pace back and forth and can neither sit down to read or play or sleep. In severe cases, patients appear continuously agitated.

Akathisia is felt to be an unusual manifestation of the Parkinsonian syndrome. Goldman (3) points out that this condition occurs often without recognizable anxiety that can be verbalized.

Akathisia, then, can be defined as a variation of the Parkinsonian syndrome in which the patient is in a state of motor restlessness which may appear like an anxiety state but in which real anxiety can be neither recognized nor verbalized. This syndrome has recently been brought to widespread medical attention as the result of the introduction of a new tranquilizer, trifluoperazine (Stelazine). A significant number of patients are reported to develop akathisia during treatment with this drug.

Freyhan (5), in an as yet unpublished paper, has reported the occurrence of this syndrome during the administration of other phenothiazine drugs such as prochlorperazine, triflupromazine, and perphenazine. This is to be expected in view of the fact that the Parkinsonian syndrome is a well-known side effect of the phenothiazine derivatives and appears to be directly re-

lated to the dosage of the drug. Two cases have recently come to my attention in which akathisia, without other evidences of Parkinsonism, has occurred during treatment with large doses of phenothiazine drugs.

Case 1.—Patient B. C. had suffered injury to his left eye approximately 20 days prior to admission for treatment of a corneal ulcer. There had been a great deal of pain and a certain amount of apprehension about entering the hospital. By the time a psychiatrist was called, the eye was in good condition, and the pain had disappeared. The psychiatrist was called because the patient was pacing the floor, could not sleep, and had remarked "I feel like jumping out the window." During the psychiatric interview, he stated that since admission to the hospital he had become increasingly "nervous." He was usually reasonably well in the morning but became more hyperactive as the day progressed. He could not sit in any one place, paced the hall, could not sleep, and became quite fearful that something was happening to him. His own words can best describe his feelings, "When I sit there, I feel I should be sitting here. When I sit here, I feel I should be sitting there." With this increased motor behavior and restlessness, there was no mood change, no real apprehension, no depression. There was no disturbance of thought content. The patient just could not understand why he felt the way he did.

Examination of his chart revealed that he had been given increasing doses of tranquilizing drugs in an effort to control his "nervousness." At the time he was seen, he was receiving 8 mgs. of perphenazine (Trilafon) t.i.d. in addition to 100 mgs. of promazine (Sparine) q.i.d.

It was felt that this patient was in a state of akathisia. All tranquilizing drugs were stopped immediately. Chloral hydrate was given as a sedative, and Cogentin was started empirically in doses of 2 mgs. at bedtime for 3 days only. Within 24 hours the patient was markedly improved, and within 24 hours more he had no remaining symptoms of anxiety, tension or restlessness.

Case 2.—Patient J. P. a 20-year-old single white girl, was admitted to the psychiatric unit as an emergency because of bizarre behavior at home. She was found to be mildly

¹ 326 South Main St., Akron 6, Ohio.

hyperactive, hostile, aggressive, and delusional. Chlorpromazine (Thorazine) was started in dosages of 200 mgs. per day and was quickly raised to 800 mgs. per day. With the increase in dosage, there seemed to be a paradoxical effect in that she became much more hyperactive and disturbed. Her hostility diminished markedly, but she suffered extreme dryness of the mouth and had to drink water constantly. She could not sit still, constantly moving from one seat to another, leaving the room and returning, and essentially having a flight of ideas. The dosage of Thorazine was quickly diminished to 200 mgs. per day and then 100 mgs. per day, and Cogentin was added to the regimen in dosages of 2 mgs. per day. There was some improvement in the hyperactive behavior, but the delusions and hostility became prominent again. Thorazine was discontinued altogether and trifluoperazine (Stelazine) was begun in doses of 2 mgs. t.i.d., continuing the Cogentin. Within 36 hours, the motor restlessness abated, the dryness of the mouth disappeared and the expression of delusional and hostile material diminished markedly. The psychotic process, however, remained basically unchanged; and following a reasonable trial period of drug therapy, the patient was referred for insulin treatment.

SUMMARY AND CONCLUSIONS

1. The syndrome of akathisia has been defined and described. It appears to be a manifestation of the Parkinson syndrome.

2. Two cases of akathisia are reported. They both occurred during administration of phenothiazine tranquilizing drugs, and were relieved by changing or stopping the drug and by adding an anti-Parkinson drug. No attempt was made to determine the

necessity for adding the anti-Parkinson drug when the tranquilizer was changed, though Kruse(4) reports that "these reactions . . . were always controllable" by anti-Parkinson drugs alone.

3. Akathisia is a syndrome which occurs during the administration of high doses of tranquilizing drugs. Whenever a patient fails to respond to the administration of high doses of these medicines or when he seems to have a paradoxical effect from them, the possibility of akathisia should be considered and appropriate treatment instituted.

4. Appropriate treatment of the condition appears to be, at this time, a reduction or change in the tranquilizing drugs used, plus the addition of an anti-Parkinson drug such as Cogentin, Pagitane, or Kemadrin.

THE REACTIONS OF GENERAL PRACTITIONERS TO A PSYCHIATRIC ABSTRACTING SERVICE¹

RUSSELL N. CARRIER, M.D., ROBERT S. GARBER, M.D.,²
AND CYRIL M. FRANKS, Ph.D.³

In the spring of 1957 a series of seminars entitled Psychiatry for the General Practitioner was sponsored by the Carrier Clinic in conjunction with the Mental Health Committee of the Medical Society of New Jersey and the New Jersey Chapter of the American Academy of General Practice. The abstracts of the 18 papers presented aroused so great an interest and brought such a demand for copies that, with the aid of Smith, Kline and French, some 26,000 copies had to be printed and distributed throughout the country. Because of this widespread, and somewhat unexpected, interest an informal follow-up survey was carried out. It became readily apparent that, although the general practitioner was at times virtually inundated with pamphlets and literature of every description, there was a need for some form of abstracting service by means of which selected parts of the mass of technical psychiatric literature, written by one specialist for his equally special colleague, might be translated into more generally comprehensible language and consequently become of value to the general practitioner.

To meet this assumed need the Carrier Clinic of New Jersey introduced a quarterly publication entitled *Abstracts of Psychiatry for the General Practitioner*. The first issue appeared in the spring of 1958; it contained 30 one-page abstracts, culled from the recent world psychiatric literature. Some of the abstracts were relatively non-technical summaries of highly technical research or clinical contributions; others were essentially condensations of utilitarian, technically sound, but not very technical, articles from a variety of sources not readily available to the general practitioner. Casual

contact with a small sample of the 9,000 or so recipients of the journal suggested that many general practitioners would prefer the latter type of article, i.e. strongly utilitarian and of immediate aid in their everyday practices. The second issue was modified accordingly and the articles selected primarily on this basis. For example, topics treated in the second issue covered such diversities as the use of specific new medications, problems of addiction to tranquilizers, the psychiatric aspects of multiple sclerosis, the role of the psychiatrist in the treatment of Parkinson's disease, the differential diagnosis of momentary loss of consciousness, the psychiatric symptoms masking brain tumor, the treatment of the neuroses in general practice, rehabilitation of the blind geriatric patient and the counseling of parents of mentally defective children. All of these topics raise problems which the general practitioner might well encounter in his daily routine.

At this stage it became apparent that the only way to evaluate and compare these two issues and to find out what the general practitioner really requires from an abstracting service—if he requires it at all—was to carry out a systematic survey. Accordingly 496 names were selected at random from the 9,000 mailing list and a brief questionnaire was sent out, accompanied by an explanatory letter and a stamped and addressed reply envelope. The questionnaire was anonymous and had only 10 items, some of which required a Yes/No type of reply, others a rating and some brief written comments.

Of the 496 questionnaires sent out, only 52 were returned. This 10% return is consistent with physician reply ratios obtained under similar circumstances by other investigators. The question now arises of how representative of the general sample of 496 are the 52 who replied. It might be speculated that only the more interested and therefore, perhaps, the more favorably

¹ Read at the 115th annual meeting of The American Psychiatric Association, Philadelphia, Pa. April 27-May 1, 1959.

² The Carrier Clinic, Belle Mead, N. J.

³ New Jersey Neuro-Psychiatric Inst., Princeton, N. J.

disposed would bother to reply. To investigate this possibility, 30 additional randomly selected general practitioners were interviewed either directly or by telephone and essentially the same questions asked, but in considerably more detail. Although this group is small, and hence subject to some reservations in drawing any conclusions, the trend of their replies failed to differ significantly from those of the larger sample who responded to the written questionnaires. On the contrary, the resemblances were striking, suggesting that the 52 written replies may be judged as reasonably representative of *Abstract* readers in general.

Of the 52 returned questionnaires two were blank, one because of the decease of the physician concerned and one for no apparent reason. Of the remaining 50 questionnaires most, but not all, were fully completed. Hence the number of replies varied slightly from question to question. Most, but not all, general practitioners recalled receiving both issues, some few recalled receiving neither. One respondent checked "neither," then, in an invited comment question, strongly complained of this failure to send him the journal and finally, in a question which called for suggested improvements, complained bitterly that the journal was "far too technical and complex." Fortunately such curious inconsistencies were rare and it was reassuring to observe that almost everybody who reported receiving both issues had taken the trouble to look at both issues.

Most of the replies were very much in favor of the *Abstracts* and their continuation, provided that the articles were of utilitarian value in general practice. Apparently what is required is guidance in a do-it-yourself program with some indications of its limitations and the sort of psychiatric cases and occasions when specialist help must be sought. If replies such as "helps me to evaluate and attempt to take care of patients that would ordinarily have to be sent to the psychiatrist immediately" are indicative of things to come, then, perhaps, not all psychiatrists will be as appreciative of this new service as are the general practitioners.

Comments were repeatedly expressed to

the effect that the general practitioner is primarily interested in concise, practical articles which will be of value to him in his practice. He is not, in general, interested in keeping ahead of current research developments or new theories. Above all, he wants the articles to be abstracted in a language which is as devoid of technicalities or psychiatric jargon as possible, especially psychoanalytic terms. Perhaps not unnaturally, this veto does not apply to pharmacological or general medical jargon; in other words, abstracts must be readily comprehensible to the general practitioner and utilize his *own* jargon, not any one else's.

From Table 1 it is clear that the *Abstracts* has made some impact upon those who received it and that the second, and more practical issue, is the more popular—although a surprisingly large proportion of readers apparently have no strong preferences. Both questionnaire and interview techniques confirmed that the present format is satisfactory in almost all respects and that a quarterly journal containing some 30 abstracts is ideal.

One of the more revealing questions was that in which the physicians were asked to rank 4 different topic areas in order of interest and then add further comments if they felt so inclined. Both statistical ranking and additional comments indicate that there is a distrust and an aversion to many psychoanalytic concepts as well as a lack of interest.

It may be of interest to record briefly some particularly relevant findings from a related but independent study which is to be reported elsewhere. In a recent survey of reactions to the second Carrier Clinic Seminar Series of Psychiatry for the General Practitioner, held in the fall of 1958, questionnaires were sent out to those general practitioners who had attended part or all of the lecture program. Eighty-nine questionnaires were sent out, 59 replies were received. The 12 questions were similar to those asked in the *Abstracts* questionnaire and, once again, strict anonymity was preserved.

Before discussing these replies a note of caution must be sounded. The information obtained from this questionnaire was in-

h. Ranked order of interest of the following four topics :	
1. psychosomatic medicine	47*
2. treatment of psychiatric patients by the g.p.	15*
3. drugs	6*
4. psychoanalysis	1*

*Note : These figures are not percentages, they are obtained as follows : For each topic the number of times the topic was placed first was divided by the number of times it was placed last. These four ratios were then expressed in terms of the smallest as unity by dividing throughout by the smallest, the final figures being corrected to the nearest whole number.

tended to help in the presentation of an even better third seminar series in the future. Since the 89 recipients were already sufficiently interested in psychiatric problems to take the trouble to attend at least part of the preceding seminar series, they can, in no sense, be considered a random sample from the population of general practitioners. It is therefore hardly of value, or surprising, to learn that over 90% of the replies indicated strong interest in psychiatric problems and a desire to receive further material provided that it were prepared specially to meet their needs. What is of significance is the answers received to questions concerning specific topics for future discussions. The needs expressed here coincided almost precisely with the needs expressed in the Abstracts questionnaire and many suggestions obtained which would be of value in the future planning of both Seminars and Abstracts.

A strong interest was expressed in the

many problems associated with the management of the mental defective and his relatives. Other physicians were concerned about their lack of knowledge of the subtleties of office interview and treatment techniques. As one physician confessed,

I feel a little inadequate in office interviews, where my stethoscope, thermometer, and examination table are removed. Also, in treatment, where my hypo needle, prescription blank, etc., are taken away. What can you do to help me? Your course has already helped a lot and your publicity angle with the newspapers has let many of my former patients know I was interested. They now come expecting more time and interest. What can you do to help me further in helping these people?

In the Seminar survey, as in the Abstracts questionnaire, it became apparent that, as a group, general practitioners are primarily interested not in research, theoretical principles or abstract cases but in specific

problems, their recognition and their treatment.

Returning now to the *Abstracts* questionnaire, many useful suggestions were received. Although most physicians were apparently satisfied with the existing procedure, several readers suggested that each issue be confined to one or two subjects which could then be treated more thoroughly. Other specific suggestions occurring more than once were for the inclusion of articles on the therapeutic use of hypnosis, on the management of problems relating to mental deficiency, on medico-legal problems pertaining to mental abnormality, on the differential diagnosis of retarded, brain damaged and schizophrenic children and articles on the treatment by the general practitioner of specific disease entities and specific psychiatric problems, especially the mildly neurotic patient.

Several physicians commented sadly that their medical school training had provided them with little or no psychiatry and that this gap became more and more apparent as their office practice increased. What many physicians apparently require is some guidance in interviewing techniques and the methods by which danger signals may be recognized in time. One problem which seems to arouse much anxiety in the general practitioner is that of the patient's anxiety, how to avoid its arousal and how to cope with the situations when it occurs. An associated problem is how best to avoid manipulation by certain patients.

Running through the responses to the Seminar survey, to the *Abstracts* questionnaire and to the direct interviews were a small number of comments pertinent to the general practitioner's personal reactions and to the gradual development of insight following exposure to basic psychiatric concepts and modes of thought. One general practitioner, although not in these words, discussed the problems of counter transference and the gradual realization of the important part that he himself played in the treatment of a particular patient, even though the ailment was primarily a physical one. This was particularly brought home to him during one period when he did not feel well himself and was conse-

quently inclined to be terse and irritable in his dealings with patients. Gradually he awakened to the fact that his patients were getting very little out of their visits to him on these occasions and that they weren't even responding to simple suggestions relative to the method of taking their medication. This physician went on to report how meaningful it was to begin to understand his own emotional attitudes towards his patients.

Another physician commented that he was now able to recognize that he became persistently annoyed with a particular patient whom he had hated for many years. As a result of the literature he had read and the Seminars he had attended he is now able to realize much more clearly what had been happening between himself and the patient he had despised so much. This physician further reported that, with his change of attitude, he was able to sense a positive response on the patient's part.

A number of general practitioners reported that they felt terribly guilty about seeing patients with psychiatric problems, or confirmed neurotics. They recognized that actually they did not want to see them and they felt uncomfortable about carrying patients along for a prolonged period of time and giving them nothing more material than "talk" to help them with their illnesses. Each of these general practitioners then related that he is now much more aware of his necessary role in the patient's treatment and that, since he has reattained this awareness, he has been able to change his own attitudes towards his patients. The first practical step taken as a result of this developing insight was a rescheduling of office visits to allow more time for discussion of the many emotional factors involved.

The report of one physician is worthy of direct quotation. It reads as follows:

I have been doing many of these things in my relationships with my patients all my life and never gave myself any credit for it. Now that I have some understanding of the mechanisms involved I am certainly going to give myself credit—so now I like myself better.

SUMMARY

In conclusion and summary then, the

Carrier Clinic Abstracts of Psychiatry for the General Practitioner seems to be fairly successful in meeting a recognized need of the general practitioner for practical information and guidance about commonly encountered psychiatric disorders. It is apparently also serving a function which is not quite as well recognized as a need by the average general practitioner—namely the need to develop partial insight into personal reactions and into doctor-patient interactions regardless of the nature of the presenting complaint.

The editors and abstracting committee would be advised to develop their searching and abstracting techniques in two different directions. First, they have to recognize that a wealth of practical material of direct value to the general practitioner sometimes lies obscured beneath a mass of technical detail and highly professional idiom which is frequently only intelligible to the specialist and his specialized cohort—and sometimes not even to them. It is the task of the editors to discover, translate and edit the relevant portions of these articles and present them to

the general practitioner in readable, yet still accurate, form. Second, they have to seek out, condense and collect under one roof the more significant of those non-specialist psychiatric articles which lie scattered from time to time throughout the 3,000 or so medical journals which appear regularly somewhere in the world. Here the problems are primarily those of wise selection and good condensation.

From the point of view of prospective authors the urgent need seems to be for concise and up to date information on the various problems associated with state and voluntary commitment procedures for mental patients. The other area where more articles are required is that of practical "know-how," a sort of do-it-yourself manual for the family physician who has to cope with a wide variety of direct and reactive neurotic conditions in his general practice. Included in this latter type of article would be the provision of information and warning signs which might advise the physician when to consider seeking more specialized psychiatric help elsewhere.

FACTORS IN THE SUCCESS OF A PUBLIC MENTAL HEALTH PROGRAM

MAURICE E. LINDEN, M.D.,² KENNETH E. APPEL, M.D.,³
JOHN E. DAVIS, M.D.,⁴ AND ROBERT A. MATTHEWS, M.D.⁵

PROBLEMS

The current popularization of mental illness as one of the country's leading problems of health, coupled with a widespread intensification of interest in the conservation of mental health and the prevention of mental illness, has alerted communities to the need for public mental health programs. The last decade has witnessed the development of a number of such programs which in many instances have enjoyed less than hoped for effectiveness owing to a variety of factors, the most important of which follow.

1. *Widely prevalent gaps and deficiencies among preventive, therapeutic and reconstructive services.*—The common experience, as related by mental health administrators in many places, has been an almost universal tendency to develop extensively those services that are traditional and easily understood. Therapeutic programs, institutionally oriented as a rule, although in short supply, are much more readily available than preventive and reconstructive programs. The discontinuity of service thus realized tends to limit the total value of therapeutic efforts and to permit a fairly extensive rate of relapse among patients served. The effectiveness of the mental health program prior to 1956 in Philadelphia in terms of treatment services can be approximately measured by an average year's experience of the Philadelphia General Hospital, psychiatric division. This unit has served as the major admission resource for most citizens seeking public

psychiatric care, and during the past several years has treated some 1,800 patients per year. Two-thirds of these patients have been returned to the community in various stages of improvement after an average stay of about 40 days. The relapse rate computed on the basis of readmissions within a year has been about 20%.

2. *Administrative divergence among agencies responsible for various aspects of program, including failure in mutual intercommunication.*—In most populous localities mental health activities are found in a great variety of agencies. Therapeutic services are generally offered in state operated inpatient facilities, voluntarily operated inpatient general and psychiatric hospitals, clinics under multiple auspices, specialized units under the courts, under public and private health agencies as well as in numerous service groups ranging from care for dependent and neglected children under Welfare Departments to family service agencies. Customarily such service units are autonomous and are relatively unrelated programwise to analogous facilities throughout the community.

3. *Absence of definitive information about communities' mental health needs and resources.*—Professional and non-professional organizations attempting to translate the mental health needs of a given community into service units have almost uniformly discovered a scarcity of accurate local demographic, prevalence and incidence statistics as well as a paucity of valid formulae for the development of new units or the expansion of old ones.

4. *Omission of a centralized multipurpose official mental health agency capable of integrating and coordinating the network of communications.*—Many communities desirous of establishing and developing mental health programs have discovered the absence of a unifying body; or, where present, such mental health agency is often found to be limited in its scope of influence and operations.

⁵ Professor of Psychiatry, Jefferson Medical College, Philadelphia, Pa.

FIRST STEPS

The Commonwealth of Pennsylvania and its major metropolitan area, Philadelphia, undertook in 1952 and thereafter to correct the obstructing factors. The resultant experience in mental health programming possesses unique elements of cooperation, integration, and coordination, which may well merit the attention of planning bodies desirous of establishing mental health programs.

The first significant events were the following :

1. *The utilization of a comprehensive public health survey of Philadelphia.*

The local health and welfare council accomplished a survey and report now known as "The Philadelphia Public Health Survey of 1949." Among its 192 unusually apt recommendations was the suggestion, widely supported, that there be either a Bureau or a Division of Mental Health in the City. This report later served as an important reference point in the development of an intensified municipal public health program.

2. *The metropolis' acquisition of a "Home Rule Charter" by referendum.*

The citizens of the municipality adopted a new city charter in 1952 which provided the basic administrative structure for the renaissance of a great city and also provided the philosophical foundation for municipal government capable of devoting efforts to services to people. Since the city and county of Philadelphia are identical geographical regions, the charter provided for the abolition of the bulk of county governmental offices, thus making it possible for the City to negotiate directly with the State in the establishment and joint support of tandem services.

3. *The arrival of City and State administrations dedicated to the establishment of service programs.*

The City of Philadelphia in 1951 and the Commonwealth of Pennsylvania in 1955 elected governmental administrators, who, among a variety of community interests, were dedicated to improving the overall mental health program. The foresightedness, courage, and perseverance of the officials involved helped make into a reality the mental health program reform.

4. *The development of a Mental Health Division within the City's Department of Public Health.*

In 1954 there was established within the Public Health Department of the city its first

mental health division. Its main function was to become a medium of expression of the organizational and related needs of mental health agencies that already existed in the community and whose services and functions could be enhanced through a central coordinating body affording a focal point for all mental health programs. The division recognized its further responsibility to insure the provision of adequate services and clinical facilities to meet the community's needs, supplementing the resources of voluntary organizations or higher governmental agencies as required and to the extent possible.

5. *Legislative establishment of a State Office of Commissioner of Mental Health in the Department of Welfare.*

The traditional position of Commissioner of Mental Health had been that of consultant to the Secretary of Welfare. A new law, enacted in 1955 establishing the new position of Commissioner of Mental Health with a 5-year tenure of office, gave the Commissioner full authority to initiate and coordinate mental health programs throughout the Commonwealth in accordance with defined needs.

An informed and aroused public, embarrassed by national statistics and local conditions which had given the State a rather poor grade on the national mental health report card, found its voice in joint relationships among the many agencies whose coordination and integrated programs have now created some models of efficiency. Historically, the state mental health unit located in the Department of Welfare had encountered uniform difficulty in attempting to establish local progressive mental health programs throughout the Commonwealth. This was largely owing to the absence of a local planning and programming body to which the state unit could relate its activities.

The City of Philadelphia, a community of over 2½ million people in a State of about 11 million, for many years felt that it had not received a fair return from its tax contributions through a prorated proportion of mental health services. As a consequence there was a chronic state of disagreement between the two echelons of government. The mental health services available to the community were grossly inadequate. In an effort to rectify this situation and because the city had developed a receptive

unit ready to integrate mental health services, officials from the state and the city met to determine how best to merge their respective plans and resources.

In 1955 the state legislature allocated to the Dept. of Welfare a large sum of money to improve the overall mental health program and to bring into every community within the state a mental health program that could really meet local needs. A merger between the state and the city programs became a reality in July, 1955. In order for such merger actually to take place it was necessary at the outset to create unitary leadership over the two programs. The director of the city's division of mental health was appointed to serve concurrently in the capacity of regional director of the state mental health program. The region was designated as the City of Philadelphia.

Under such unitary direction it became possible to integrate the two programs, while keeping their major aspects discrete. The community program became almost exclusively preventive and rehabilitative mental health, while the state program provided in- and outpatient services and clinical facilities.

Prior to the merger, Philadelphia could boast of only 268 beds at its disposal for the admission and intensive treatment of psychiatric problems arriving from all quarters of the municipality. The city each year was able to process some 1,700 or 1,800 patients from a potential resource of over 150,000. This meant that for every patient accepted for inpatient services, about 5 to 10 were returned to their homes without immediate care. As a rule only the most seriously ill patients were accepted. In addition, the one state hospital in the city, originally built to house some 4,300 patients, had a swollen census of approximately 6,700 patients without additional facilities. As a consequence a balance had been struck between the Philadelphia General Hospital psychiatric unit and the State Hospital so that about 10 patients per week were transferred from the General Hospital to the State Hospital. This rate was maintained no matter how urgent became the needs of the community.

Prior to the merger the city also had the

equivalent of about 18 psychiatric outpatient clinics mostly for children. About 43 were needed. In general few needed services in the field of public mental health were available.

In accordance with the principle of first things first, emphasis of the merged program was placed initially on the needs of the mentally ill; in most instances needs for hospitalization. The endorsement of the new program in 1955 by the psychiatric departments of the city's 5 medical schools, the state hospitals in and about the city, the involved general hospitals, the psychiatric and psychoanalytic institutes, clinical agencies, the voluntary and official health and welfare units as well as responsible authorities made it possible to regionalize the mental health program as well as to develop cooperative services. A mental health orbit and a pattern of communications were established.

THE CONJOINT BOARD

The regional director's first step was to create a governing board of control over the local program. This planning body became known as the Conjoint Mental Health Board and was made up of the following individuals: the State Secretary of Welfare, the City Commissioner of Public Health, the City Commissioner of Public Welfare, the State Commissioner of Mental Health, the Regional Director, the Executive Director of the City General Hospital, the Superintendent of the Philadelphia State Hospital, the Executive Director and chief health consultant of the Health and Welfare Council, the Professor of Psychiatry of the University of Pennsylvania, the Executive Director of the regional Mental Health Association, and the Executive Director of the Eastern Pennsylvania Psychiatric Institute.

At the outset the Conjoint Board met weekly, sometimes oftener, in order to facilitate program development. Individual meetings were long and the debate extensive. An atmosphere of freedom for "talking and thinking through" the complexity of problems was regarded a *sine qua non* in order to develop the objectivity required by the leadership of a merged group of

independent agencies. Later the Board met monthly on a regular schedule.

For the purpose of unifying admissions to various units, of evaluating incoming patients and making the best possible use of existing facilities, a reception center was created at the City General Hospital. Thirty-two beds were later made available here. This unit was staffed with several complete mental health teams able to perform intensive, high caliber, rapid diagnostic screening. Whereas this unit was obligated to receive and evaluate all individuals referred to it, it was not obligated to hospitalize them. A policy was established that where hospitalization was postponed or obviated, some further care was provided. This eventuated in a referral program as well as an outpatient service operating at the center and offering follow-up as well as definitive therapies as indicated. The education and indoctrination of all community agencies and improved utilization of all existing mental health facilities were effected in large measure through the clinical activities of the reception center.

As an outlet for the Reception Center, an orbit of 4 clinical inpatient units was established consisting of the following: the psychiatric unit of the Philadelphia General Hospital with 268 beds, the Philadelphia State Hospital with its acute and intensive therapy and admitting unit of 285 beds, the Eastern Pennsylvania Psychiatric Institute with a potential of 50 beds for children and 250 beds for adults, and a 100 bed psychiatric unit for adults and youth at the Mercy-Douglass Hospital operated under the psychiatric department of the University of Pennsylvania School of Medicine with funds received from the State Dept. of Welfare.

The reception center was placed organizationally under the Philadelphia Regional Office which represents the point of liaison between the state and the city. In Philadelphia the program was created before the administrative device. Thus it may be said that the administrative device was the creature of the program. The Conjoint Mental Health Board supervised the entire program and became the topmost policy making group in its administration. This still operating Board is "unofficially offi-

cial" and has gained considerable status in the community. It may be thought of as analogous to a mental health authority. The Board's recommendations have been traditionally regarded as directives by the State Department of Welfare.

Since in 1955 the State Secretary of Welfare and the State Commissioner of Mental Health had assigned authority to the Conjoint Mental Health Board to pass on grant-in-aid requests coming from any mental health agency in the community, the Board developed a subordinate project-evaluating unit known as the program and allocations committee, which was made up of the regional program staff and appropriate community and professional representatives.

The direct operation of the reception center at the outset was under a board of control known as the admissions and policy board. This group consisted of the junior opposite number of the major administrator of each clinical unit represented in the total orbit of facilities, plus the staff of the regional program. An additional advisory unit was established under the admissions and policy board and was designated the sub-committee on services to emotionally disturbed children. Several *ad hoc* committees were likewise established for circumscribed areas of program. The considerations and deliberations of the various units, as well as the specialized experiences of their members, constituted a kind of built-in self evaluative device for the entire operational program.

PROGRAM EFFECTS

The major mental health program that followed upon the inception of the various planning units was developed in most instances without need for special legislation. Important benefits were realized quickly. When the program began, on any single day in Philadelphia there were about 150 so-called "mental patients" in the city's prisons. They consisted of epileptics, mental defectives, the retarded and psychotics of various age groups. To remove such patients from the correctional institutions, it was necessary to make room in the local state hospital.

Three regional private facilities were

brought into the program through state subsidization via a boarding-out program. A private mental hospital, a private hospital for the care of the aged and chronically ill, and a well equipped and operated nursing home were pressed into service. Each accepted 50 patients from the public mental hospital for an agreed upon daily stipend. Appropriate aged and long-term patients were selected and transferred to the newly participating units.

Almost immediately it became possible to remove to the new units persons who had been placed in protective custody in the prisons and who came under the jurisdiction of the mental health program. Subsequently all patients placed by the lower courts in temporary custody in prisons were directed to clinical services in a matter of hours through the mental health program, and it has been possible to keep out of prison mentally ill persons without criminal complications. At a later date, when the boarding-out program was no longer necessary, it was still possible to process the mentally ill through the reception center and to keep them out of jail.

As increasing numbers of persons utilized the mental health program, negotiations were completed with private mental institutions to accept at reduced rates, patients from the less favored socio-economic groups.

New preventive and rehabilitative services within the community were introduced, including an intensification of the city's preventive mental health program utilizing a variety of public education methods, systems for professional development, and counseling and advisory services in educational institutions as well as maternal and child health units. In addition, mental health units were established in each of the city's district health centers while a mental health home visit and home care program was established making use of the traditional cooperating disciplines of psychiatry, psychology, psychiatric social work and public health nursing to which were added the public health clinical laboratory and the general medical services of public health physicians. Municipally operated mental health conferences and clinical services were established for pre-school

age children throughout the city. The "open door policy" was introduced in the state hospitals, and a vast "remotivation" program was developed for long-term patients.

Rehabilitation units in the community, including modified half-way houses, vocational guidance centers and sheltered workshops as well as specialized residential care units of various types, were pressed into service for all age groups, with special emphasis upon the readaptation to community living of discharged patients from regional institutions.

SERVICES TO AGE GROUPS

The needs of the mentally ill aged received particular attention. Voluntary and official agencies undertook to improve the standards of care in nursing homes and homes for the aged while training devices for superintendents and administrators of care facilities for the aged were developed and employed. A number of carefully developed and interlacing studies of the needs of an aging population were completed by several participating units with the result that there emerged new methods of dealing with the problems of older people as well as new systems of financing with public funds. A truly unique cooperative venture among the State Department of Welfare, the City Department of Public Health and the City Department of Recreation brought into being a health oriented preventive mental health service for older adults; known as the Adult Health and Recreation Center.

The member units of the public mental health program merged with counterpart agencies serving youth and succeeded in establishing a large scale group psychotherapeutic program for juvenile offenders and cases of misbehavior. Responding to the advancing needs of a growing mental health program, the public school system of Philadelphia developed two mental health units among its intrinsic services. One of these was designed for short term psychiatric counseling to teachers, while the second served as the diagnostic, evaluating and screening unit for the emotional needs of selected school children, effecting referrals to clinical facilities as indicated for protracted therapy. Group treatment

methods were introduced into the correctional institutions under the Philadelphia Department of Public Welfare as well as in the probationary units under the municipal courts.

A vast survey of mental health facilities available to the community eventuated in the publication of a Mental Health Directory and Handbook of Mental Health Facilities which was widely distributed to appropriate persons and agencies in the entire Philadelphia Metropolitan area. The latter measure made possible better utilization of a wide assortment of available mental health agencies whose services and programs thus became better known to the professional disciplines.

PROCEDURAL CHANGES

New systems of commitment, referral and transfer were promoted. Outstanding among the latter was the development of a petition procedure initiated by the City's division of mental health, approved by the municipal courts and honored by the Police Department which authorized the use of the police-ambulance service for the conveyance of involuntary patients to the reception center for diagnostic evaluation in emergency situations. Cooperation was solicited and readily obtained from the legal departments and courts of both echelons of government. Innovations in services and procedures whose necessity was validated were sanctioned without delay.

The psychological, research and statistics units of the mental health division of the city and of the state's regional program joined forces in establishing and maintaining statistical control over the entire program. A variety of research projects was embarked upon. The results of such studies served as continuous guides to further programming. Clinical centers under voluntary auspices were expanded and extended wherever possible. Federal, state and local funds were directed to appropriate units with the result that outmoded facilities were enabled to rebuild and build anew in-service units for all age groups. Voluntary general hospitals were encouraged and aided in the development of inpatient psychiatric units.

Since the 5 medical schools of the city

had merged psychiatric interests at the Eastern Pennsylvania Psychiatric Institute while the mental hospitals and the reception center programs converged at the Conjoint Mental Health Board, and since the people of the city as well as the interests of all other psychiatric facilities and related agencies joined forces at the Division of Mental Health, the axis of these 3 units, Division-Board-Institute, constituted the nerve center of the regional mental health program.

THE RECEPTION CENTER

Undoubtedly one of the most outstanding features of the entire regional mental health program has been the establishment of the reception center operated under state auspices and located in the Philadelphia General Hospital. This unit began operation the middle of 1958. Its program and activities have mushroomed to an unprecedented degree. Its 1958 statistics are testimony to the importance to the community of this unit. In that year the reception center treated 5,087 patients, 4,012 of whom were first admissions and 1,047 re-evaluations. In addition this unit conducted 2,846 follow-up visits. After beds were made available in May of 1958, the reception center itself served 934 patients on an inpatient status and released such patients to the community. To accomplish its services this unit employed 8 full-time and 2 part-time psychiatrists, 8 residents for night and weekend service, 1 internist, 2 full-time psychologists, 3 full-time social workers, 6 registered nurses, 7 practical nurses, 15 attendants, 3 food workers and 8 clerks.

It is to be noted that each of Philadelphia's 5 medical schools (plus about 70 other establishments) conducts outpatient psychiatric clinics where patients requiring hospitalization are seen. The professors of psychiatry state that the fact that the reception center exists as a distribution point to other hospitals has been a great service to the clinics and has saved much staff time. In addition to patients being referred from clinics related to the teaching hospitals, patients requiring in-service care frequently are brought to university receiving wards. Through the division of mental

health the help of the Police can be readily obtained and has often been of great value.

An additional example of the cooperative relationship among participating units in the regional program is the utilization of the reception center as a source of patient material for research projects being conducted by the medical schools or other academic units. The 4 inpatient facilities that constitute the regional mental health orbit provide adequate facilities for psychiatric teaching in medical centers. Many additional services, programs, and projects have been in operation as a development of the program, but their description is not within the scope of this paper.

The program has gained momentum with the result that greater numbers of persons receive treatment earlier and are returned to community effectiveness sooner than was predicted by even the most optimistic observers. The success of this program was achieved largely through the better utilization of existing facilities.

NEW PROBLEMS

While the mental health program to a large extent represents a successful venture in which the community and its surrounding Commonwealth take considerable pride, it is well to point out that each solution to a problem has usually uncovered new problem areas. Facilities for the inpatient care of children are still present in inadequate numbers; emotionally disturbed children tend in numerous instances to back up into units inappropriate for their care. Therapeutic and preventive services for the aged are still available in only token measure. More public mental hospital beds are still needed in this geographical area. Consideration is now being given to the question of building new state psychiatric units as against the possible subsidization of voluntary facilities. Budgetary limitations continue to modulate the growth and progress of the program. Increasing effectiveness and popularity of the program bring ever increasing numbers of patients to the mental health units, thus producing bottlenecks, with the result that emergency care becomes protracted for many individuals for whom hospitalization would probably be more desirable.

Perhaps one of the most attractive features of the program has been its use of bits of programs and services operating in many places and which have been incorporated into a unified overall operation. The following are a few examples. The inspiring success of England's state institutions encouraged the local mental hospitals to open many wards; the home care program has been patterned to a considerable extent along the lines of that in operation in Amsterdam, Netherlands; the experience of the State of Massachusetts with respect to services for the aged was used early as a blue-print for the Philadelphia program; a foster care program patterned after that in Maryland has been found eminently successful in caring for substantial numbers of former inpatients; the programs of New York's recreation centers for the aged were emulated in developing the adult health and recreation center in which the novel feature has been the incorporation of psychiatric and other medical and surgical services, consultations and referrals; New Jersey's Menlo Park experience with youth in trouble served as a guide to the state-city regional program for youngsters with behavior problems; a New York unit of identical name was emulated in Philadelphia's Fountain House community readaptation program; the day center principle of Montreal was studied for local development; and Ohio's program on mutual patient transfers between homes for the aged and mental institutions was duplicated locally.

SUMMARY

The following factors have likely been paramount in the operational success of the Philadelphia regional mental health program:

1. Excellent timing of the program coinciding with the peak development of interest and goodwill on the part of an informed public and dedicated governments;
2. Intensified and continuous communication among popular representatives, professional staffs and political bodies;
3. Creation of two important cooperating governmental mental health units—the

Philadelphia division of mental health within the Department of Public Health and the State of Pennsylvania's office of the Commissioner of Mental Health within the Department of Welfare (now Public Welfare);

4. Establishment and continuation of the Conjoint Mental Health Board;

5. Creation and intensification of the programs of the reception center;

6. Maintenance of continuous and perpetual statistical control over all aspects of the program;

7. Constant application and initiation of

various researches and surveys including program self-reevaluation;

8. Attention to all of the community's mental health needs in a comprehensive program;

9. Utilization of operational elements proved effective in other localities (profiting vicariously from others' mistakes);

10. Involvement of the lay and professional communities wherever possible;

11. Encouragement of leadership at the lowest possible echelon of responsibility in the overall administrative pattern.

12. Giving credit where due in public and press relations.

CLINICAL NOTES

PSYCHOPHARMACOLOGICAL AGENTS: A SELECTIVE SURVEY¹

JAMES P. CATTELL, M.D.²

Each drug is listed as follows: chemical (generic) name, rating (see below), registered name and manufacturer, range of daily dosage, side effects and general comments.

Rating Scale: Each drug is rated according to the following system:

Effectuality:	Toxicity and Side Reactions:
Good-1	Mild-A
Fair-2	Moderate-B
Poor-3	Marked-C

Thus, an effectual drug with minimal toxicity and side effects is designated: 1A; an ineffectual drug with marked side effects or toxicity: 3C

I. The Neuroleptics (used primarily for psychomotor agitation).

A. Phenothiazine Derivatives:

Chlorpromazine, 1B (Thorazine-SKF), 25-250 mg. q.i.d. Jaundice, liver damage, agranulocytosis, urticaria, contact dermatitis, photosensitivity, GI syndrome, Parkinsonism, akathisia, convulsive seizures, depersonalization, depression, hypotension, drowsiness, fatigue and cataleptic seizures reported. Possibility of liver damage warrants greatest caution.

Promazine, 2B, (Sparine-Wyeth), 50-250 mg. t.i.d. Same side effects as chlorpromazine. Less photosensitivity and jaundice but higher incidence of seizures.

Mepazine, 2C, (Pacatal-Warner-Chilcott), 25-50 mg. t.i.d. Same side effects as chlorpromazine but possibly more agranulocytosis, seizures and atropine-like action. Regarded by some as

ineffectual and too toxic for general use.

Prochlorperazine, 2B, (Compazine-SKF), 5-30 mg. t.i.d. Fewer side effects than chlorpromazine but higher incidence of Parkinsonism, akathisia, dyskinetic syndrome.

Perphenazine, 2B, (Trilafon-Schering), 2-6 mg. t.i.d. Fewer side effects than chlorpromazine but marked akathisia and dyskinetic syndrome as well as convulsive seizures, cataleptic attacks in children and galactorrhea and angioneurotic edema. Relative effectuality: controversial; regarded as equal to chlorpromazine by some.

Promethazine, 3A, (Phenergan-Wyeth), 100-150 mg. daily. Harmless and ineffectual.

Trifluoperazine, 2B (?), (Vesprin-Squibb), 100-150 mg. daily. Relatively new. Agranulocytosis already reported. More data needed.

Trifluoperazine, 2A (?), (Stelazine-SKF), 1-8 mg. t.i.d. Fewer side effects than chlorpromazine. Parkinsonism, akathisia, dyskinetic syndrome, agitation and turbulence prominent—mostly controllable by anti-Parkinsonian drugs or reducing dosage. Further data needed.

Thiopropazate, 2B, (Dartal-Searle), 2-10 mg. t.i.d. Parkinsonism, akathisia and dyskinetic syndrome prominent. More data needed.

Piperidinochlorphenothiazine, 1C, (NP 207-Sandoz). Produced retinal degeneration during investigation phase. Never marketed.

Acepromazine, ?B or C, (Notensil-Crooks-Barnes?), ? dose. Hypotension, seizures, loss of peripheral reflexes. (Has been withdrawn from investigation?).

Thioridazine HCl, 2A, (Mellaril-Sandoz), 25-200 mg. t.i.d. (TP 21—when under investigation.) More data needed.

B. Rauwolfia Alkaloids:

Reserpine, 2B, (Serpasil-Ciba; also other

¹Based on literature available about each drug as of June, 1959 and our experience at the Columbia-Presbyterian Medical Center. Dr. Sydney Malitz, Acting Chief Research Psychiatrist, N. Y. State Psychiatric Institute has made a significant contribution to the application of the rating scale in the survey. His cooperation and assistance are appreciated.

²Assistant Clinical Professor of Psychiatry, College of Physicians and Surgeons, Columbia University.

companies), 0.5-1 mg. b.i.d. Jaundice and agranulocytosis not reported. Skin reactions, Parkinsonism, akathisia, dyskinetic syndrome, seizures, depression with suicidal ideation, depersonalization, hypotension, drowsiness, fatigue, excitement, edema and rupture of peptic ulcer reported.

Deserpidine, Canescine, Recanescine, 3B, (Harmonyl-Abbott), 0.24-2 mg. t.i.d. Fewer side effects claimed than with reserpine. Further data needed.

Rescinnamine, 3B, (Moderil-Pfizer), 0.25-0.5 mg. b.i.d. May be as effectual as reserpine but with fewer side effects. Further data needed.

II. The Tranquilizers (for anxiety-tension states).

A. Diphenyl Methane Derivatives :

Azacyclonal, 3B, (Frenquel-Merrill), 200-400 mg. daily. An analogue of pipradol HCl. Introduced as an anti-hallucination and anti-confusion drug. Value not confirmed. Animal experiments indicate it may produce hepatitis and pancreatic lesions.

Benactyzine, 3B, (Suavitil-Merck) 1-3 mg. daily. Contraindicated in "hostile" patients. May produce concentration difficulty, depersonalization, paresthesias, muscle weakness, dizziness, tension, nausea, vomiting, dry mouth, diarrhea, ataxia, palpitation, apathy, indifference. Recently combined with meprobamate (Deprol-Wallace) as an antidepressant-rating : 3B.

Hydroxyzine, 2A (P), (Atarax-Roerig), 10 mg. t.i.d. Of questionable value except in very mild anxiety. No side effects yet reported.

Phenyltoloxamine, 2A (P), (PRN-Bristol), 25-50 mg. b.i.d. Boston Psychopathic Hospital study on normals : Useful in relieving muscular tension and has sedative effect without motor or intellectual impairment. No autonomic or visual side effects. (Perhaps this drug should be listed with the non-barbiturate sedative-hypnotics in Section IV.)

B. The Substituted Propanediol Group :

Meprobamate, 2B, (Miltown-Wallace ; Equanil-Wyeth), 200-400 mg. t.i.d. No convincing studies demonstrating the superiority of tranquilizers to barbiturates. Meprobamate medication associated with production of fever, malaise, nausea, vomiting, headache,

increased peristalsis, cardiac dysrhythmia, hypotension with shock, rashes, angioneurotic edema, purpura, itching, drowsiness, euphoria, restlessness, hypomanic conditions, diplopia and coma. Addiction and withdrawal syndromes reported. Potentiates alcohol, barbiturates and antihistamines.

Phenaglycodol, 2A, (Ultran-Lilly), 300 mg. t.i.d. Said to allay anxiety without dulling mental acuity or awareness. Further data needed.

C. Other :

Chlormethazone, P, (Trancopal-Winthrop), 100 mg. t.i.d. Primarily a muscular relaxant, with tranquilizing action. Further data needed.

III. Stimulants (Anti-Depressives) :

A. The Hydrazines :

Iproniazid, 2C, (Marsilid-Hoffman-La-Roche), 10-25 mg. t.i.d. (1-isonicotinyl 2-isopropyl hydrazine). Anti-depressive value varies : 30-90% improvement reported. Side effects : dizziness, ataxia, loss of muscular tonus, hypotension, accommodation disturbances, headache, dry mouth, flushing, sweating, euphoria, confusion, restlessness, depression. Edema, dyspnea, cardiac failure and neuralgic pain also reported. Acute yellow atrophy of the liver has been reported by several investigators—with a number of fatalities.

Phenelzine dihydrogen sulfate, P, (Nardil-Warner-Chilcott), 15 mg. t.i.d. (B-phenylethylhydrazine dihydrogen sulfate). Reported to be less toxic than iproniazid but as effectual in relieving endogenous depression. Hypotension, nausea, ankle edema, transient impotence and micturition reported.

B-phenylisopropylhydrazine HCl, P, (Catron-Lakeside, 12-3 mg. daily.³ All of the hydrazines inhibit monamine oxidase, thus protecting serotonin from being broken down. Catron reportedly inhibits brain MAO without affecting liver MAO and thus is safer than iproniazid, which affects liver MAO first. Side-effects : Hypotension, red-green visual defect, may be potentiating with other MAO inhibitors, may mask coronary insufficiency and overdose can produce liver damage.

To be released for sale soon.

Nialamide, P, (Niamid-Pfizer), P dose,

³Initial and maintenance dosages.

(N-isonicotinoyl-N'-B-[N-benzyl-carboxamido] ethyl hydrazine). Under investigation. Reportedly a potent antidepressant that is effective within a few days and is relatively free of adverse side effects. Not yet released.

B. The Amphetamines :

Dextroamphetamine, 2B, (Dexedrine-SKF), 2.5-10 mg. t.i.d. Side-effects : Anorexia, insomnia, palpitation, anxiety and feeling of being "driven." Non-toxic when used in therapeutic doses under medical supervision. Contraindicated in patients with cardiovascular disease.

Dextroamphetamine with amytal, 2A, (Dexamyl-SKF), dose : same as above (includes 30 mg. amobarbital per 5 mg. D-amphet.) D-amphetamine side effects minimum or absent if dose is properly adjusted. Effect is to allay anxiety, relieve depression and facilitate integrated functioning. Often neutralizes depersonalization phenomena.

Methamphetamine, 2B, (Desoxyn-Abbott), 2.5-5 mg. t.i.d. Effectuality and side effects lie between dexedrine and dexamyl.

C. Other Anti-Depressives :

Methylphenidate HCl, 2B, (Ritalin-Ciba), 5-10 mg. t.i.d. This drug and pipradol reportedly do not produce the unpleasant side effects of the amphetamines. Actually, they do. A shock-like condition may develop with tremor, sweating, tachycardia, headache, vertigo, motor restlessness.

Pipradol HCl, 2B, (Meratran-Merrill), 1-2.5 mg. t.i.d. May produce insomnia, nausea, skin rash. May aggravate existing anxiety and produce psychotic phenomena. Said to be contraindicated in patients with anxiety, hyper-excitability, paranoia, agitation and obsessive compulsive states. Some investigators report that the amphetamines are more effectual than either of these preparations.

Deanol, 3B, (Deaner-Riker), 25 mg. t.i.d. The few available reports find this drug useful in mild depression. The rating given reflects that impression at the N. Y. State Psychiatric Institute.

Imipramine, 1B, (Tofranil-Geigy), 25-75 mg. t.i.d. Beneficial in endogenous depressions. Use with neuroplegics in agitated depressions suggested. Most side effects occur in patients receiving more than 200 mg. daily. One-third of 84 patients (Lehmann) had side effects of the following types : Hypotension, seizures, tremors, diplopia, involuntary staring, visual hallucinations, agitation. Side effects more common in patients over 65. This drug is a monamine oxidase facilitator—in contrast to the hydrazines.

IV. Non-Barbiturate Sedatives and Hypnotics :

Methylparafynol, 2B, (Dormison-Schering), 250-500 mg. b.i.d.

Glutethemide, 1B, (Doriden-Ciba), 125-250 mg. t.i.d.; 500 mg. hs.

Ethchlorvynol, 2B, (Placidyl-Abbott), 250-500 mg. b.i.d.

Methpyrrolon, 2B, (Noludar-Hoffman, LaRoche), 50-200 mg. b.i.d.

Oxanamide, 3B, (Quiactin-Merrill) 800-1000 mg. daily.

Ethinamate, 2A, (Valmid-Lilly), 500 mg. p.r.n.

These drugs are recommended by their respective producers as being as effectual as the barbiturates but free of the possibility of habituation. In addition, there is said to be no hangover the morning after; e.g., drowsiness, haziness, and fatigue. There may be less of the latter in the case of some of them. None is as effectual hypnotically as secobarbital and amobarbital for sleep disturbances for which these are usually prescribed. Most of these newer preparations present the disadvantages of barbiturate daytime sedation : drowsiness and fatigue.⁴ Other side effects : Dormison : dizziness, mood lability, irritability, depression, distortion of time sense and body image, amnesia and vomiting. Doriden : drymouth, itching, dermatitis, nausea and, most important : increasing tolerance, addiction and severe withdrawal symptoms : abdominal pain, restlessness, panic and clonic spasms.

ISOCARBOXAZID (MARPLAN) IN AMBULATORY PSYCHIATRIC PATIENTS

HARRY F. DARLING, M.D.¹

The use of isocarboxazid in hospitalized patients has been previously described (2). This paper describes its use in 25 private ambulatory depressed patients and 5 schizophrenics. Three of the schizophrenics were mixed with affective components, and 2 were catatonics. Except in the case of 2 of the chronic brain syndromes the depressions were of relatively recent origin (3 to 15 months), and the remaining cases of depression were as recent. Initial dose for the depressed patients varied between 20 mg. and 60 mg. daily, and mean maintenance dose was 30 mg. daily. The schizophrenics were given 30 mg. daily for a week and only then increased to 60 mg. in an attempt to decrease the incidence of initial side effects; mean maintenance dose was 40 mg. daily. All cases were under treatment 3 or more months. Improvement is shown in the accompanying table.

One schizophrenic had been hospitalized 10 months in the psychiatric unit of a Veteran's Administration hospital and received group and individual psychotherapy—and nothing else. He was sent out of the hospital in the hope that he might adjust in society and with the recommendation that if he did not he should go to a chronic rehabilitation hospital. A personality change had been going on at least 7 years. After 2 weeks specific treatment his affective component cleared up and he began not only working but also occupying himself in home handicraft projects of a technical nature. His other schizophrenic features rapidly receded and he and his family feel he is as good as, if not better than, he was 7 years ago. The other schizophrenics had noted disturbing symptoms for one to 8 years. One catatonic improved markedly, another moderately. The unimproved schizophrenic was one with affective components.

The obsessive-compulsive patient was

particularly interesting in that the results confirmed the findings of Arnot (1) who noted improvement in all 5 cases of this disorder treated with hydrazines.

Side effects included 2 patients with hypotension, alleviated by a pressor agent, and one with hypotension and equilibrium disturbance who could not tolerate even 10 mg. daily. One case of edema was controllable by diuretics and the other was not; both were aged.

The drug began to act within 3 days to 4 weeks of treatment.

DISCUSSION

Nothing need be said about the depressed patient that has not already been said about hydrazine therapy, but regarding the schizophrenics there is now a total of 12 cases treated by the writer (2) and 8 by an associate (4), not including the vegetative group previously reported (2). Six of these cases improved markedly, 5 moderately and 3 minimally. Improved cases have been catatonics and mixed-affectives, more of the former. Even in relatively low doses iproniazid has been shown—in a very scientifically controlled and objective paper by Freymuth (3)—to improve 50% of chronic and regressed schizophrenics. In the confusing array of literature on neurohormones it has been shown by Sano (5) that chlorpromazine elevates serotonin, and it is possible that part at least of the effect of phenothiazines on the brain may be much more tangent to that of hydrazines than we realize. In the writer's opinion hydrazines are the treatment of choice in schizophrenics who have affective components, although by no means the first choice in catatonics, but should not be overlooked if other methods are not working well. In the writer's opinion high doses are indicated for optimum results and seem to be possible with isocarboxazid.

Diagnosis	IMPROVEMENT				
	No. Cases	Marked	Moderate	Minimal	None
Anxiety neurosis	10	4	3	1	2
Obsessive-compulsive	1	1	0	0	0
Involuntional	2	1	1	0	0
Dyssocial reaction	1	1	0	0	0
Depressed manic	3	3	0	0	0
Chronic brain syndrome	8	3	1	2	2
Schizophrenia	5	3	1	0	1
Total	30	16	6	3	5

SUMMARY

Isocarboxazid appears to be a very workable hydrazine derivative for treating ambulatory depressions, and is of use as well in certain cases of schizophrenia. Relatively high doses are possible with relatively few side effects. The isocarboxazid for this study was supplied by Roche Laboratories (trademark, Marplan).

PROBLEMS IN EVALUATION OF R-1625

HERMAN C. B. DENBER, M.D., PAUL RAJOTTE, M.D., AND
DOROTHY KAUFFMAN, R.N.¹

Several continental investigators have reported unusually successful results in the treatment of acute and chronic psychotic patients with 1-(3-*p*-fluorobenzoylpropyl)-4-*p*-chlorophenyl-4-hydroxypiperidine (1-3).² The absence of a phenothiazine nucleus and its ability to produce extrapyramidal reactions in a large percentage of patients suggested the desirability of further trials.

Thirty acute and chronic female patients (ages 23-61) were studied under standard conditions (*i.e.*, daily observations; weekly team review; laboratory studies). They were hospitalized 10 days to 5½ years, and diagnosed for the most part as dementia

praecox; 3 were manic-depressive. Presenting symptoms extended from maniacal excitement to depression, while moderate to severe thought disorders were present.

The initial dose ranged from 1 to 10 mg. t.i.d. with 14 patients receiving between 1-3 mg. t.i.d. At the end of the study, 15 patients were receiving between 5 and 30 mg. t.i.d. The duration of treatment was: 1-19 days—9 patients; 20-59 days—11 patients; 80-100 days—5 patients; more than 100 days—5 patients. An extrapyramidal syndrome was the most frequently observed side effect (12 patients), was fairly incapacitating, requiring anti-Parkinson drugs. There were no abnormal changes in the white or red blood counts; bilirubin, cephalin flocculation or thymol turbidity tests. The total blood cholesterol was elevated in 2 patients. R-1625 had no blocking effect upon mescaline.

¹ Research Division, Manhattan State Hospital, Ward's Island, New York 35, N. Y., and College of Physicians and Surgeons, Columbia University, New York, N. Y.

² R-1625 was provided through the courtesy of Dr. Thomas H. Hayes, G. D. Searle & Company, Chicago, Ill.

The results were: much improved—4; improved—5; unchanged—21. Psychotic behavior in some patients was intensified with increased anxiety, restlessness and additional symptoms. Three of the 4 much improved patients were depressed and showed rapid disappearance of this affect between 27 days after medication was started. Acute psychomotor agitation was refractory even where the drug was given intramuscularly in high doses (5 patients).

DISCUSSION

Improvement in depressed patients on the research ward has at times been observed without any treatment other than the intensive social therapeutic program. For this reason, we cannot be absolutely certain that R-1625 was the effective agent. This is the first time a compound has been studied with the present group of patients which produces fairly severe extrapyramidal symptoms, and yet has relatively little therapeutic effectiveness.

Our inability to confirm the European results raises several interesting questions which cannot be definitely answered at present. It is necessary to compare (a) the patient population, (b) dose range, (c) criteria for improvement, and (d) the investigator's technique. The latter has been considered elsewhere(4). Items "a" and

"c" were approximately identical (personal observations), and our doses were in excess of those used by others(1-3). Finally, it was supposed that the product used was not identical to that furnished abroad(5).

The absence of any blocking action against mescaline supports previous comparative observations with other more effective drugs.

SUMMARY

It was not possible to influence the clinical picture in 21 of 30 acute and chronic female psychotic patients following treatment with R-1625.

HEAT STROKE WITH MEPAZINE THERAPY

WALTER L. FORD, M.D.¹

The report by Mahrer, Bergman and Estren, "Atropine-Like Poisoning Due To Tranquilizing Agents," in the October 1958 issue of *The American Journal of Psychiatry*, seemed to indicate that further information regarding this subject should be published. During the summer of 1957 the VA Hospital, Waco, Texas, had as many as 150 patients on mepazine (Pacatal). A warm spell enveloped Waco with temperatures as high as 105 degrees F. During that period we had over 25 patients who were

receiving mepazine develop heat strokes. Some of the patients developed temperatures as high as 108 degrees F. In each case the role of mepazine, in rendering the patients susceptible to heat stroke, was recognized, as the pharmaceutical company distributing the drug warned in its literature about hyperthermia. In each patient the drug was discontinued immediately, and the usual treatment, that is, ice packs, etc. for heat stroke, was administered. There were no fatalities. We have had no similar experience with patients receiving other phenothiazine derivatives.

IMPROVED TECHNIQUE FOR INDOKLON CONVULSIVE THERAPY

WILLIAM KARLINER, M.D., AND LOUIS PADULA, M.D.¹

Since we(1) introduced the use of Pentothal and Anectine for modification of Indoklon² inhalant convulsive therapy, certain technical problems have arisen. The following is a brief summary of our observations and a recommendation for improvement of this technique.

Esquibel and coworkers(2) used a modified Stephenson mask for Indoklon convulsive therapy. This method seemed satisfactory since the patient was not anesthetized. But if Pentothal and Anectine were used, patients were breathing only shallowly because they were under anesthesia. It took more time and a greater amount of the inhalant vapor to produce a convulsion with Indoklon. Furthermore, the protective effect of Anectine was gone in many instances at the time when the patient responded to the inhalation of Indoklon with a grand mal seizure.

To overcome this difficulty, we had the container holding the Indoklon attached on one side to the mask, and on the opposite side to a rubber bag which was connected

by a rubber tube to an oxygen tank. This enabled us to control the amount of oxygen which was mixed with the Indoklon vapor. By manual pressure on the rubber bag, it was possible also to force the Indoklon vapor into the patient's lungs while he was under Pentothal anesthesia.

This technique overcomes the apprehension experienced by some patients when receiving gas inhalation in any form. It insures the proper timing of the patient's convulsive response to the Indoklon-oxygen vapor mixture, thus enabling the patient to benefit from the softening effect of Anectine. It is important not to use too much oxygen because its use decreases the potency of Indoklon, delays the onset of the convulsion, and necessitates deeper anesthesia, larger amounts of Indoklon and the loss of benefit from Anectine. This method is safe and very simple, and its adoption for Indoklon convulsive therapy is recommended.

A COMPARISON OF REST AND ECT IN THE TREATMENT OF SCHIZOPHRENICS

PETER D. KING, M.D.¹

The importance of evaluation of psychiatric treatments by careful measurement and comparison cannot be overemphasized. Early in my still brief psychiatric career I resolved, among other things, to attempt such evaluation. The result was several published and unpublished reports, one of which(1) showed significant worsening of hospitalized chronic schizophrenics 6 months following "regressive" electroshock (REST). These patients had been given

one or more series of ECT earlier in their hospitalization and some of them had received insulin coma therapy. The question remained to be answered if hospitalized chronic schizophrenics who had never had somatic treatment would benefit from either ECT or REST. A subsidiary question regarded the comparative efficacy of ECT and REST in both chronic and other schizophrenics. This paper offers an answer to each of these questions.

METHOD

Thirty-seven schizophrenic males were

¹ Clinical Director and Director of Research, Madison State Hospital, Madison, Ind.

randomized into 2 groups: one group received ECT 3 times a week (ECT) and the other received it twice daily 6 days a week (REST). Both groups received a total of 20 treatments. Eighteen of the patients were chronic² schizophrenics who had never before had a series of ECT and 19 were subacute³ schizophrenics. The 18 chronic schizophrenics came from chronic wards in a "Kirkbride" type of building; they and the 19 subacute schizophrenics were all placed on the treatment ward of the building. Treatment was completed just prior to routine staff changes; this was done so that the new administering physicians would not know that a study was in progress. They became aware that treatment had been given and were responsible for the convalescence of the patients—typically seeking to release them or place them on the "better" wards. Because of this, I felt that ward "quality" and rate of release would be satisfactory

² Patients at Warren State Hospital, Warren, Pa. who had been hospitalized continuously for an average of 15 years.

³ 3 patients who had just been re-admitted after previous hospitalization, 4 recently admitted patients who had received somatic treatment on the acute treatment service and failed to recover, and 12 new patients who were admitted from prison.

measures of response to treatment. Evaluation was made 6 months after the last treatment.

RESULTS

REST produced marked confusion in all patients who received it, and resulted in one death (apparently from ventricular fibrillation, but autopsy permission was not granted). Six months following treatment there was no apparent difference between the two groups. Nine chronic schizophrenics fell in each group; none had been released from the hospital and all of them were on wards at the same level as those they had come from, or "worse." The only noticeable improvements were among the 18 surviving subacute patients: 2 in each group had recovered and been released, while 3 on ECT and 2 on REST had been given open ward privileges.

In summary, ECT and REST showed no significant difference in the treatment of schizophrenics, and neither was of any apparent benefit to chronic schizophrenics who had never before had either.

METHYLNONYL DIOXOLANE: A CLINICAL TRIAL

CALVIN SCHORER, M.D., AND PAUL LOWINGER, M.D.¹

The dioxolanes are a group of substances related structurally to meprobamate, and pharmacologically to mephensin. One particular member of the group, 2-methyl, 2-nonyl-4 hydroxy methyl 1-1, 3-dioxolane, has been studied. Like the other dioxolanes, it appears to suppress excessive stimulation of spinal interneurons. Direct, or two-neuron, pathways are not affected, but more elaborate reflexes, such as the

flexor reflexes, are blocked. No effect on respiration or consciousness was reported in preliminary animal studies (1, 2, 3). Spasm, tremor, or other involuntary movements accompanying anxiety, therefore, seemed appropriate indications for a clinical trial of methylnonyl dioxolane, referred to as MND.

The study was made with a group of psychiatric outpatients characterized by obvious signs of anxiety, particularly in the motor sphere, i.e., tremor, muscular tension, or tics. They were first given a complete psychiatric examination and such other adjunctive examinations as seemed appropriate. This preliminary evaluation defined the patient's suitability for a drug clinic ac-

¹ From the Lafayette Clinic and Wayne State University College of Medicine, Detroit, Mich. This investigation is a part of a project supported by Public Health Service Research Grant MY-2241, National Institute of Mental Health. The National Drug Company, Philadelphia, furnished the 2-methyl, 2-nonyl-4 hydroxy methyl 1-1, 3-dioxolane (methylnonyl dioxolane).

conform to criteria outlined by Lowinger *et al.*(1).

Twenty-three patients took MND for a period ranging from 7 to 140 days; the mean duration of treatment was 45 days. The patients' ages varied from 19 to 66 years. Thirteen were female, 10 were male. Diagnostically, the patients showed a considerable variety, including 10 psychotics (7 schizophrenics, 1 manic-depressive, depressed), 2 motivational reactions, 10 psychoneurotics, 2 personality disorders, and 1 psychophysiological reaction.

The patients had MND prescribed orally in 750 to 1000 mgm. amounts daily in divided doses. Return appointments were given in one to 4 weeks. The physicians serving in the drug clinic recorded the patients' degree of anxiety, sleep disturbance, depression, thought disturbance, and the quality of interpersonal relationships. To heighten objectivity, each of these symptoms was graded from one to five on standardized rating sheets; this allowed us to establish a numerical description of relief from symptoms. A clinical progress note at the time of each return appointment gave a verbal account of symptoms, side effects and current reality events, and the dosage of the drug was modified according to the patient's response. When several weeks on high dosages had elapsed without benefit, or when ordinary dosages resulted in side effects or a demand for other medication, MND was discontinued.

Side effects appeared in 7 of the 23 patients. The most common side effect, nausea and vomiting, was also found in

earlier studies of a nearly identical diuretic, Glyketal(3). Irritability and bad dreams were the less common side effects attributed to MND. All 4 instances of nausea and vomiting, and 5 of the total of 7 side effects, occurred among schizophrenics.

The effectiveness of MND in each patient was determined by means of a review of the rating sheets and progress notes recorded at each clinic visit. The following results were obtained: little or no improvement, 5 patients; moderate improvement, 10; marked or complete relief, 8. Neurotics, followed by schizophrenics, were the diagnostic groups with highest relief scores. Anxiety was the symptom best relieved, and insomnia was second best.

In conclusion, this study shows definite relief of anxiety symptoms but with a high incidence of side effects, particularly in schizophrenic patients. Tremors and tensions are the symptoms best relieved; nausea and vomiting are the usual side effects. The drug appears worthy of clinical trial for selected patients.

TREATMENT OF DRUG-INDUCED EXTRAPYRAMIDAL HYPERKINETIC REACTIONS WITH UK-738

(N-ETHYL-NORTROPINE-BENZHYDRYLETHER-HYDROBROMIDE)

RUPERT H. MAY, M.D.,¹ MAURICE B. RULAND, M.D.,² AND
MARGARET R. GOLD, B.A.

Drug-induced hyperkinetic states, including restlessness and hyperactivity, hysteriform head-neck syndromes resembling spastic torticollis, and pseudo-Parkinsonian

reactions, are frequently seen accompanying treatment by psychotropic drugs, especially phenothiazines. They may decrease or disappear with maintenance or decrease of the dosage, but frequently persist on required medication levels.

Atropine and related substances, used in

¹ Cleveland Psychiatric Institute and Hospital, Cleveland 9, Ohio.

² Hawthornnden State Hospital, Macedonia, Ohio.

the treatment of extrapyramidal hyperkinetic reactions, have been largely replaced during the past decade by chemicals unrelated to naturally occurring Atropine, because of the complex action of Atropine, the primarily one effect, the control of rigidity and tremor, was desired.

We tested a new compound of the Atropine group,³ n-ethyl-nortropine-benzhydry-

l-ether-hydrobromide (UK-738)(1) as an anti-hyperkinetic agent. UK-738 does not contain tropic or any other acids, nor a free hydroxyl group. Different physiological reactions, therefore, could be expected.

In animal studies(2) the tolerable dosage range was smaller for UK-738 than for Atropine (Table 1). However, inhibition of pilocarpine-induced hypermotility (intestine in situ, cat) was 6 times weaker than that of Atropine; inhibition of salivation evoked by pilocarpine (rabbit) 10 times weaker; mydriasis-inducing effects (mouse) 14 times weaker. The central effects, like potentiation of the excitatory effect of amphetamine or potentiation of pentothal anesthesia were stronger with UK-738. In rats, cataleptic reactions produced by phenothiazines were inhibited by UK-738. UK-738 is an anticholinergic agent with strong central and weaker peripheral action.

The compound was used in 30 volunteer patients, for as long as 2 months. Twenty-four exhibited a pseudo-Parkinsonian reaction due to phenothiazines. Twenty-three of these showed a sufficient decrease of Parkinsonian symptomatology, usually within 48 hours, on dosages of 0.5 mg. b.i.d. to

2 mg. b.i.d., orally, despite continuation of phenothiazine therapy. Tremor and rigidity disappeared. Salivation decreased to appropriate levels, questioning elicited an occasional report of mainly nocturnal oral dryness. The Parkinsonian facies was replaced by normal facial expressions. A quicker response was obtained by subcutaneous injection of 0.5 to 1 mg. in those patients unable or unwilling to swallow. One patient experienced no relief but improved when UK-738 was replaced by Cogentin. Such a substitution was made in 7 additional patients. Six responded equally well, one failed to maintain the improvement achieved with UK-738. Upon withdrawal of Cogentin, after 3 weeks and under continued phenothiazine dosage, recognizable Parkinsonian features reestablished themselves soon in these 8 patients.

Five patients exhibiting marked drug-induced restlessness and one manifesting a hysteriform head-neck syndrome were treated similarly with UK-738. Improvement was always satisfactory, often occurring within 20 minutes. Small single dosages (0.5-1.0 mg.) provided beneficial effects lasting from 4 to 12 hours.

No undesirable side reactions, except for the occasional oral dryness mentioned, have been noted within the respiratory, cardiovascular and intestinal systems, on routine laboratory tests, and in the mental status examinations. The mydriatic effect was absent or mild. One patient on combined drug therapy and ECT required less Sodium Pentothal and less Anectine while on UK-738. Constipation accompanying phenothiazines was insufficiently affected by either UK-738 or Cogentin.

HAIRY TONGUE IN PATIENTS RECEIVING PHENOTHIAZINES : PRELIMINARY REPORT

A. E. PAGANINI, M.D. AND M. ZLOTLOW, M.D.¹

In the voluminous literature concerning the side effects and complications of the phenothiazine derivatives, no report has appeared of the occurrence of hairy tongue in patients receiving these drugs.

At Pilgrim State Hospital, in September, 1957, a patient who was receiving chlorpromazine in doses of 1,200 mg. per day complained of severe dryness of the mouth. Experimentation revealed a hairy tongue. After discontinuance of therapy, the hairy tongue disappeared within 2 weeks. Subsequently, all patients complaining of excessive dryness of the mouth were watched for this development. In March of 1958, another patient complained of excessive dryness of the mouth while receiving chlorpromazine, 900 mg. per day and mepazine, 150 mg. per day, and again a classical hairy tongue was discovered.

Following this, a group of 896 patients were examined specifically for this finding. Nineteen more patients were found with a hairy tongue, giving a total of 20. All these patients were seen and the diagnosis confirmed by the consulting dermatologist.²

Of the 20 patients with this condition, 3 were on no drugs whatsoever, but the remaining 17 patients were receiving chlorpromazine and/or mepazine. The hairy tongue disappeared in 5 drug-treated patients after the discontinuance of therapy. The rest of the patients (12), are still receiving phenothiazine derivatives and to this date still retain the hairy tongue. All these patients have been receiving medication for at least 2 months, some for over one year.

As noted in the indiscriminate survey of patients, 3 cases of hairy tongue were discovered among those receiving no medication. Two of these patients, however, chew tobacco almost constantly. The other one was a heavy smoker and all 3 had poor oral hygiene.

Smears and cultures taken from all 20 patients have been confusing and contradictory. Most samples show a normal mouth flora with gram positive cocci predominating, but occasionally an indiscriminate specimen would show the presence of *B. coli*, *Candida Krusei* or *Candida Stellatoidea*.

Case Report.—A 54-year-old dentist was admitted October 15, 1957; his seventh admission to a psychiatric hospital. On admission, the patient was overactive, overtalkative, gesticulated wildly, and was obviously in increased psychomotor activity. He was diagnosed as manic-depressive psychosis, manic type as on all his previous admissions. He was placed on chlorpromazine, 200 mg. twice daily; he responded adequately and was released convalescent status December 24, 1957. However, the patient failed to continue his medication after release from the hospital and was readmitted December 30, 1957, again in an obviously manic state. The patient was again given chlorpromazine in doses of 300 mg. t.i.d., and on January 29, 1958 mepazine, 50 mg. t.i.d. was added. On this combination his manic symptoms abated. On March 25, 1958 the patient complained of excessive dryness of the mouth and a hairy tongue was found. The condition was confirmed by dermatological consultation. Despite this condition, the medication was continued until April 7, 1958 when the patient developed severe depression and psychomotor retardation. At this development the drugs were discontinued and within one week the hairy tongue disappeared.

COMMENTS AND SUMMARY

1. In an indiscriminate survey of 896 patients at Pilgrim State Hospital, 20 patients possessed a hairy tongue.

2. Three of these patients were on no drugs whatsoever.

3. Seventeen patients were on chlorpromazine or chlorpromazine and mepazine.

4. Five of these 17 patients lost their hairy tongue after discontinuance of medication.

It obviously cannot be stated definitely

¹ Box A, West Brentwood, N. Y.

² Acknowledgment is expressed for the help and suggestions rendered by Abraham Zelony, M.D., Consultant in Dermatology, Pilgrim State Hospital.

that the phenothiazines cause hairy tongue. But, as noted above, the 5 patients whose medication was discontinued lost their hairy tongue within 2 weeks. The rest of the patients still retain their hairy tongue while receiving their medication. This seems to point the finger of suspicion toward the phenothiazines, especially in view of the well-established concept that other drugs, notably the antibiotics, have been found to cause this condition. The occurrence of the 3 cases of hairy tongue in patients receiving no medication also points

out the possibility of this being purely coincidental. In addition, there lurks in the background of all these patients the fact that most of those with hairy tongue possess poor oral hygiene and are heavy smokers or tobacco chewers.

Further studies of this problem are being carried out in an attempt to correlate all these findings. The observation is considered to be of interest and importance and is, therefore, reported in this preliminary study as a possible complication in the use of phenothiazine drugs.

CASE REPORTS

EMBOLIC CEREBRAL SEQUEL IN RHEUMATIC MITRAL STENOSIS PRECIPITATING SENILE MENTAL DETERIORATION

WALTER L. BRUETSCH, M.D., AND CLIFFORD L. WILLIAMS, M.D.¹

The incidence of late cerebral sequelae in patients with rheumatic valvular heart disease ranges between 3 and 5 per cent. Some of these patients require hospitalization in mental hospitals.

The fundamental lesions of these sequelae consist, most frequently, of a recurrent rheumatic obliterating arteritis, mainly of the small meningeal and cortical vessels, producing gross and microscopic softenings in the cortex (1, 2). Less often, there is an embolic mechanism of these vascular occlusions, developing in patients with advanced rheumatic mitral stenosis and auricular fibrillation (3).

Case Report.—The female patient, at age 69, began having repeated slight strokes, which were followed by mental symptoms. She used vile language, tried to set fire to the house, attacked relatives and friends, and ran away from home. At the same time, she became increasingly forgetful and confused, and developed epileptic seizures, which occurred every 3 to 4 months. Prior to her mental illness, she had been considered a well adjusted and sociable personality.

The patient had had measles, mumps, and whooping cough, but there was no history of rheumatic fever. (Rheumatic antecedents, such as rheumatic fever, acute arthritis, and chorea are found in the anamnesis of patients with rheumatic heart disease in only 50-70 per cent.)

When she arrived at Central State Hospital, she was considerably improved. There were no residual signs of the former strokes. She walked into the admission room with a friendly smile, saying that she had "leakage of the heart" for a long time and was worried because she could not think properly. She thought it was 1972 and revealed other gross memory defects.

Physical examination was essentially negative with the exception of the heart. The

precordium was active. A blowing systolic (grade 2) and a low pitched rumbling diastolic murmur were heard at the apex. The pulse was 90 and irregular. The blood pressure was 130/90, rising in the two succeeding years to 190/130.

Electrocardiographic study revealed atrial fibrillation. On X-ray examination the heart was enlarged and of a mitral configuration. The Wassermann reaction of the blood was negative. There were 4,800,000 red cells and 6,200 white cells, with a practically normal differential count. The urine contained the slightest possible trace of albumin and at times an occasional granular and hyaline cast.

The diagnosis was chronic brain syndrome, associated with circulatory disturbance, rheumatic cerebral embolism, with senile psychotic reaction, complicated by grand mal seizures. She died at the age of 74 of congestive heart failure.

Postmortem Observations.—In the dilated left auricle of the heart there was a large organized thrombotic mass, firmly attached to the wall which was partly calcified. The stenotic mitral valve had a roughened closing border, and the chordae tendineae were shortened.

In the brain was a large area of infarction in the region of the right island of Reil, extending into the upper temporal and lower central convolutions, but leaving the basal ganglia mostly intact (Fig. 1). A small infarcted area was also observed in the cortex of a frontal convolution. All cerebral arteries were entirely free of atherosclerosis. Microscopic examination detected an organized embolus in a branch of the middle cerebral artery going to the infarcted area.

Embolic residuals were also present in the right kidney and in the spleen.

SCHIZOPHRENIA ASSOCIATED WITH ADDISON'S DISEASE

HAROLD D. WOLFF, M.D., AND P. E. HUSTON, M.D.¹

Present Illness: An 18-year-old man was admitted November, 1957, in his first attack of mental illness with complaints of tension, irritability, and the belief that he was being doped. The illness had developed gradually over 5 months without known precipitating events.

The mental status revealed psychomotor retardation, inappropriate smiling, poverty of thought. His content centered about lights outside the hospital being related to sputnik and that the physicians were poisoning him with tablets. There were no hallucinations. He was oriented as to place, knew the year and month, but not the date. He carried 5 digits forward and 3 backwards, replied to arithmetic problems, being frequently careless and wrong. His understanding of absurdities was satisfactory, but he could not interpret proverbs correctly, giving up easily.

The physical examination, routine laboratory work, skull and chest X-rays were normal. The EEG was slightly slow in the anterior and temporal lobes bilaterally with 4 to 6 per second theta low voltage in the waking state. No abnormality appeared in sleep or with hyperventilation.

Family History: The father had had arteriosclerotic brain disease for 5 years and caused difficulty in the home because of irritability and excessive demands. The mother was a self-deprecating woman who relied upon her children for emotional support. Two sisters were making "good adjustments." However, a 20-year-old brother had had an attack of acute undifferentiated schizophrenia in 1956 which responded well to ECT. He remains well.

Past Personal History: The early years were not remarkable, but starting in the eighth year the patient had spells of nausea, vomiting, abdominal pain, and ex-

treme weakness accompanied by "yellowing" of his skin. These spells lasted 2 to 7 days with spontaneous remission. He received no medical treatment.

The previous personality was that of a shy, but not schizoid, easygoing boy who had two close boyfriends with whom he hunted, fished, and participated in sports. He did not date during high school, but otherwise the psychosexual development was normal.

Admission Impression: Schizophrenia, undifferentiated, acute.

Course in the Hospital: Because of gradual improvement it was decided to treat the patient with supportive psychotherapy. However, after 7 days he began to grime, maintained postures for hours if left alone, and was mute. This behavior was sometimes interrupted by outbursts of combativeness and destructiveness.

Electroshock treatments were started. After 16 treatments there was marked improvement with only residuals of slight affective blunting and mild anxiety. Thorazine was prescribed in the range of 75 to 225 mgm., and after 23 days he developed swelling of the hands, wrists, and oropharynx. The drug was immediately discontinued and the swelling gradually subsided. However, 8 days after the onset of the swelling, bronzing of the skin was noted. In 5 more days he complained of abdominal pain and developed nausea, vomiting, and hypotension. The serum Na was 123, K 6.9, and Cl 88.0 (Meq/L). The 17-ketosteroid excretion was 2.5 mgm./Gm. Creatinine. These findings were consistent with hypoadrenalism. The zinc turbidity, thymol turbidity, and serum bilirubin values were normal.

As the signs and symptoms of Addison's disease progressed, the patient became withdrawn, more tense, demonstrated blocking and ambivalence. However, he

¹ Department of Psychiatry, College of Medicine, State University of Iowa, Iowa City, Iowa

had no delusions and the sensorium remained clear.

Because the blood pressure declined to 70/40 mm. of Hg., cortisone was started. Within 24 hours the hypotension, vomiting, and abdominal pain had disappeared. Within 48 hours there were no signs of withdrawal, tension, blocking, or ambivalence.

The patient was stabilized on 25 mgm. of cortisone per day. In order to rule out secondary adrenal insufficiency, cortisone was gradually discontinued and 100 units of Acthar-Gel per day were given. During the cortisone withdrawal the patient became progressively tense, withdrawn, and ambivalent, but not delusional. At this time the 17-ketosteroid excretion on 3 consecutive days was abnormally low with values of 3.1, 3.9, and 3.1 mgm. of 17-ketosteroid/Gm. Creatinine respectively. This was interpreted to indicate a primary adrenal insufficiency. His physical state was normal except for a bronzed skin. The serum Na was 138, K 4.8, Cl 108, all within the normal range. The fasting blood sugar was 98 mgm.%. The EEG became normal, and psychological studies for brain damage were within normal limits. During this period the patient was off cortisone for 5 days. Cortisone was restarted without any mental improvement after 9 days. Then DOCA, 1 mgm. per day for 3 days and 0.5 mgm. per day for 2 days, was added. Within this 5 day period his mental state became normal. The DOCA was discontinued because of edema, and the patient was finally stabilized on 12.5 mgm. per day of cortisone, which maintained improvement. At the time of discharge 20 days later, the patient's mental and physical performances were normal.

Follow-up: Examination one year after discharge revealed no signs nor symptoms of Addison's disease or schizophrenia. The patient has taken 12.5 mgm. of cortisone daily.

The patient's brother, who had had an attack of acute undifferentiated schizophrenia, underwent extensive laboratory testing in order to detect adrenal insufficiency. These tests were normal.

DISCUSSION

There have been several reports of psy-

chotic behavior accompanying Addison's disease, the psychoses in these reports being called "paranoid psychosis," "Addisonian psychosis," "confusional psychosis," "depression," "paranoid schizophrenia" (1, 2, 3). At the time of admission of our patient no one questioned the diagnosis of a schizophrenic reaction. It was only after Addison's disease appeared that we wondered whether this patient had two unrelated illnesses, or whether the schizophrenic reaction was either caused or "triggered" by the recognized metabolic disorder. Arguments consistent with either of these possibilities can be advanced.

The fact remains, however, that the institution of hormonal therapy was closely followed by a remission of the classical signs of schizophrenia. This is strong evidence of a causal relationship of Addison's disease and the mental reaction. On the other hand, we cannot readily explain why there was not prompt improvement after the second introduction of Cortisone nor why he improved mentally the second time only after DOCA was begun.

It is possible that since the age of 8 this patient has had recurrent bouts of adrenal insufficiency (4). If one postulates that this patient's adrenal "reserve" has been low for years, why did not the course of ECT precipitate an acute adrenal insufficiency syndrome? It has been urged on the basis of animal work that ECT is a severe stress (5). Two reports describe the use of ECT in the treatment of psychoses associated with Addison's disease (2, 3). In both of these instances electrotherapy was given while the patient was receiving hormonal therapy. Nevertheless, Craddock and Zeller (2) doubt that ECT represents an acute physiological stress.

SUMMARY

A patient is presented who showed an acute schizophrenic reaction. Treated with ECT, there was marked improvement. Four weeks later the schizophrenic symptoms returned accompanied by signs and symptoms of Addison's disease. Treated with hormones, there was a remission of both the Addison's disease and the mental symptoms.

After one year of maintenance on cortisone the patient is without evidence of improvement on Addison's disease.

COMMENT

INTERDISCIPLINARY TRENDS IN MENTAL HYGIENE RESEARCH AND TRAINING

(FEDERALLY SPONSORED PROGRAMS)

From the point-of-view of financial support, the research and fellowship programs established in the mental health field are largely dominated by the National Institute of Mental Health, and a large share of the progress made in the past decade has been

the result of this federal subsidy. Future trends will be, hopefully, determined by honest and careful appraisals of the past record. The data which follow are a contribution to such an appraisal.

TABLE 1

RESEARCH PROJECTS

Following is a classification of 247 research grant proposals receiving U. S. Public Health Service support in December 1958. The categories were selected on the basis of the research *methods* which were outlined in the proposals.

<i>Classification of Projects</i>	<i>Number</i>	<i>% of Total</i>
1. Psychological testing	77	31%
2. Pharmacology	39	16%
3. Animal studies	25	10%
4. Studies of metabolism	13	5%
5. Psychopathology	12	5%
6. Physiology of mentally retarded	9	4%
7. Surveys of public opinions	9	4%
8. Studies of patients' families	8	3%
9. Training of mentally retarded	7	3%
10. Follow-up studies of patients	7	3%
11. Psychotherapy	7	3%
12. Sociological (community) studies	6	2%
13. Psychosomatic studies	6	2%
14. Population surveys	5	2%
15. Electroencephalography	5	2%
16. Studies of juvenile delinquents	3	1%
17. Studies of the sensorium	1	(-1)
18. Electric Shock	1	(-1)
19. Industrial problems, psychiatric	1	(-1)
20. Personnel training	1	(-1)
21. Unclassified	4	2%
TOTAL	247	100%

TABLE 2

PRINCIPAL INVESTIGATORS

Following is a break-down of the professional specialties listed as the "principal investigators" in the research projects of Table I.

<i>Professional Specialty</i>	<i>Number</i>	<i>% of Total</i>
1. Psychologists	130	53%
2. Psychiatrists	57	23%
3. Social workers	13	5%
4. Anthropologists	6	2%
5. Biochemists	6	2%
6. Educators	4	1%
7. Pharmacologists	4	1%
8. Biologists	4	1%
9. Internists	3	1%
10. Physiologists	3	1%
11. Neurologists	2	(-1)
12. Anatomists	1	(-1)
13. Pediatricians	1	(-1)
14. Obstetricians	1	(-1)
15. Osteopaths	1	(-1)
16. Combinations	11	4%
TOTAL	247	100%

TABLE 3

FELLOWSHIP PROGRAM

Following is a list of numbers of fellowships awarded by the National Institute of Mental Health between 1952 and 1959, classified according to the department to which fellows were assigned.

<i>Department</i>	<i>1952</i>	<i>1953</i>	<i>1954</i>	<i>1955</i>	<i>1956</i>	<i>1957</i>	<i>1958</i>	<i>Totals</i>
Psychology	21	19	12	15	40	69	102	278

Others	0	0	0	1	3	28	6	38

TABLE 4

FELLOWSHIPS (N.I.H. : N.I.M.H. RATIOS)

The following shows the number of fellowships awarded in mental health as compared with the total numbers of fellowships awarded by the National Institutes of Health.

Year	Total N.I.H.	Total N.I.M.H.	<i>r</i>
1952	540	74	.14
1953	543	63	.11
1954	490	42	.08
1955	1042	48	.04
1956	1407	87	.06
1957	2153	185	.09
1958	1272	187	.16

Charles E. Goshen, M.D.,
Washington, D. C.

OFFICIAL REPORTS

REPORT OF COORDINATING CHAIRMAN, COMMITTEES ON THE TECHNICAL ASPECTS OF PSYCHIATRY

I shall not be able to give detailed information with reference to the activities of 9 standing and one Ad Hoc Committee assigned to me to coordinate. All of these committees met last fall in Washington, and 9 are scheduled to meet in Philadelphia this week; the tenth one met a few weeks ago. The majority of the committees have sponsored Round Table Programs at the Annual Meeting in 1958, and are giving similar programs during this week. Many of the committees have been collaborating with Dr. Daniel Blain and The Manpower Project. As in the past, the committee members have done much work by correspondence between the semi-annual meetings.

The Ad Hoc Committee on Education in Public Hospitals. Bernard Bandler, Chairman. The committee is working on the preparation of the brochure on the data that was collected in respect to the various patterns of education in public hospitals and the practices and techniques that have been helpful to them. Considerable data have been collected on the actual experiences of public hospitals in respect to the recruitment and utilization of psychiatrists from universities and private practice for staff training. It is hoped that the brochure will be completed within the next year.

Committee on Aging. Ewald Busse, Chairman, reports that a major portion of the Eleventh Mental Hospital Institute will be devoted to the problems of the aged. The Summer Institute in Social Gerontology sponsored by the Inter-University Council and supported by a grant from the National Institute of Mental Health has revised its fellowship policies to include psychiatrists, psychiatric nurses, and psychiatric social workers. This has been largely the result of this committee's efforts, and fellows have been chosen from the mental health professions. The grant application submitted by this committee to the NIMH entitled "Program Development

for the Psychiatric Care of the Aged" was not approved by the National Advisory Mental Health Council. This is in some respects unfortunate, but it will permit this committee to devote more of its efforts towards being an effective force in the coming White House Conference on Aging. Since there are a number of regional meetings planned to precede the White House Conference, as well as other preliminary meetings, it would appear to be important that the various district branches of the American Psychiatric Association be alerted to this development and the local committees urged to participate whenever possible.

Committee on Child Psychiatry. J. Franklin Robinson, Chairman, working in conjunction with the Committee on Medical Education, was able last fall, to secure the approval, "in principle" of a set of standards for training in child psychiatry. The standards called for 2 years of satisfactory training in child psychiatry which was to follow 2 years of satisfactory training in adult psychiatry. The training in child psychiatry was to be carried out under the direction of a qualified child psychiatrist in a qualified psychiatric facility. A child psychiatric service will include the appropriate allied professions.

Committee on History. J. Sanbourne Bockoven, has concerned itself with the following activities: 1. The preparation of a proposal for a research project to study the Historical Developments of Contemporary American Psychiatry; 2. Search for new outlets for publication of papers on History of Psychiatry; 3. The establishment of a Union Catalogue of publications of historical value. (As a first step in this direction, a bibliography of the writings of the Founding Fathers was compiled.) The Committee made the following recommendations, which were approved by Council in November, 1958: 1. That a Library illustrating the history of psychiatry be located and developed in the Founder's Room at

APA headquarters; 2. That the archives of the association be assembled and placed in APA headquarters, and 3. That the Medical Director be authorized to initiate a research project on the historical development of contemporary American Psychiatry. In addition, the Committee is investigating various approaches to study and prepare the *History on Contemporary Psychiatry*. It is seeking acquisition of books for the library. With the collaboration of Mrs. Vosburgh, the Committee has initiated an historical column in *Mental Hospital*.

Committee on Medical Education, George C. Ham, has been reviewing the two Ithaca Conference Volumes, preparatory to a decision regarding future conferences of this type, or special revisions and editions, or republications of these books. The Chairman has conferred with Central Office Staff regarding the republishing of the Directory on Residential Training Programs. The Chairman has contributed to the APA Survey of Medical Education in Alabama and in British Columbia. The Committee has sponsored a Teaching Institute at McGill University in October, 1958, and is planning future Institutes.

Committee on Mental Deficiency, Howard V. Bair, Chairman, has taken steps to establish liaison with the American Association of Mental Deficiency. It is working on a model state plan for complete community services for the care and treatment of mental defectives. It has undertaken a somewhat comprehensive review of new research in the field of mental deficiency. A conference was held with Dr. Charles Bush regarding Joint Accreditation for Institutions for the Mental Deficient. The Committee, together with the Committee on Mental Hospitals, requested Council to stress the advisability of psychiatric leadership in hospitals for the mentally ill and mentally defective; the Council reaffirmed its previous decision with reference to such psychiatric administration. The Chairman has been appointed as the official APA representative to the First International Medical Conference on Mental Retardation to be held in Portland, Maine, in July of 1959.

Committee on Public Health, John J.

Blasko, Chairman, reports the following activities: 1. State Surveys: The Committee continues to assist the APA Headquarters Staff in a Consultant Capacity. New Hampshire, Alabama and British Columbia were involved during the past year. The Committee is exploring ways and means of determining the effectiveness of past surveys. 2. Mental health teaching in schools of public health. A member of the Committee has made a study of this subject. A National Conference on Mental Health Teaching in Schools of Public Health is being organized for December 1959, and will be financed by the National Institute of Mental Health. The Committee has been asked about its activities in this area. 3. The public health psychiatrist: A study is being conducted by the Committee to determine what training is necessary in order to be considered as a public health psychiatrist. 4. Layman's Guide to a Community Health Study. Your Committee will review this guide when it is developed by the American Public Health Association Task Force. Several members of the APA Public Health Committee are on this task force. 5. Psychiatric care in nursing homes. The Committee believes that the Licensure requirements for nursing homes should include adequate psychiatric services. Further study of this important problem must await developments in the Ad Hoc Committee on District Branch Committees.

Committee on Rehabilitation, Benjamin Simon, Chairman. Among the Committee's activities during the past year have been the following: 1. Publication of AAAS Symposium on "Rehabilitation" under the editorship of Dr. Milton S. Greenblatt and Dr. Benjamin Simon (now in press); 2. (By invitation of Editors of *Progress in Psychotherapy*) a chapter in Volume IV by Dr. Simon on "New Trends in Rehabilitation" (in press); 3. (By invitation of Committee on Rehabilitation of the American Medical Association) a chapter by Dr. Simon on "Psychiatric Rehabilitation" (which is to be part of a series in the *Journal of the A.M.A.*); 4. Completion of work by Dr. Simon on "Volunteer Services to Psychiatric Patients" (to be published by the APA); 5. Continuing activity of

Interdisciplinary Study Group (Dr. Carmichael representing the Committee on Rehabilitation); 6. Election of Dr. Simon as Chairman of the A.M.A.'s Advisory Committee on Occupational Therapy Education to the Council on Medical Education and Hospitals; 7. Appointment of Chairman as Advisor on Rehabilitation to the Survey of Mental Health Resources of the State of Alabama; 8. Appointment of Chairman as Advisor on Rehabilitation to the Survey of Mental Health Resources of the Province of British Columbia; 9. Continuing representation of APA by chairman as a member of: (a) Executive Committee of the Advisory Committee on Physical Therapy Education of the Council on Medical Education in Hospitals of the A.M.A.; (b) Advisory Board of the American Registry of Physical Therapists; (c) Advisory Council of the American Occupational Therapy Association.

Committee on Research. Milton Greenblatt reports that the main activity of the Committee on Research is reflected in the Adolf Meyer Lectures, Regional Research Conferences, and APA participation in the annual AAAS meetings. Dr. W. Mayer-Gross of Birmingham, England, speaking on "Model Psychoses" gave the second Adolf Meyer Memorial Lecture. Dr. W. Grey Walter, of Bristol, England, is scheduled to deliver the 1959 lecture; Dr. Aubrey Lewis, of Maudsley Hospital, London, has agreed to give the 1960 lecture. Manuscripts derived from the Columbus, Ohio, Regional Research Conference were published in "Social Aspects of Psychiatry" No. 10 in the Psychiatric Research Reports. Publication is also planned for the Montreal and Oklahoma City Conference material. The University of Arkansas sponsored a Research Conference in February, dealing with psychiatric research by medical students and residents and a number of other conferences for 1959 are in the planning stage in such areas as Salt Lake City, Los An-

geles, Chicago and Cleveland. A highly successful "Symposium on Hallucinations" under the leadership of Dr. Louis Jolyon West was held at the December, 1958 AAAS meeting in Washington, D. C. Publication is expected soon of "Rehabilitation of the Mentally Ill; Social and Economic Aspects" presented at the 1957 meeting. Commitments have been made with AAAS to participate in their 1959 and 1960 meetings. Dr. Pasamanick and Dr. Bliss of the Committee are participating in the APA Surveys of Mental Health Needs and Resources of Alabama and British Columbia.

Committee on Therapy: Henriette Klein, Chairman, has revised the Standards for Electro-Convulsive Therapy, and is submitting the most recent revision to the Council during this meeting. Requests have been made that the Committee prepare a statement on the use of Hypnosis. The Committee feels that if such a statement be prepared it should be done in collaboration with the Research Committee and the Committee on Public Information. The Committee has undertaken two specific activities: 1. The writing of a Primer of Psychiatric Therapies and their Place in Psychiatric Practice (for internes and general practitioners), and 2. A study of the current status of Psychotherapy of Hospitalized Schizophrenics. A questionnaire has been prepared and is being revised at the April, 1959, meeting.

In conclusion I wish to emphasize the conscientiousness, zeal and enthusiasm which the members of the various committees have demonstrated during this last year. I wish to express my appreciation for their splendid cooperation and also for the outstanding cooperation of the officers and the members of the APA Staff in both the New York and Washington Offices.

Frank J. Curran, M.D.,
Chairman

NEWS AND NOTES

DR. EMIL A. GUTHEIL.—Dr. Stanley Lesse, Secretary for the Association for the Advancement of Psychotherapy, reports that the death of Dr. Gutheil, at the age of 60, occurred July 7, 1959. Dr. Gutheil was graduated from the University of Vienna Medical School and became a pupil and assistant of Wilhelm Stekel, whose works he translated into English and edited his autobiography.

He came to New York City in 1937 and with colleagues founded the Association for the Advancement of Psychotherapy in 1939. The Association embraces all schools and has 411 members. Dr. Gutheil also founded the American Journal for Psychotherapy. Among his publications are *The Language of the Dream* (1939) and *Handbook of Dream Analysis* (1959).

ALBERT EINSTEIN MEDICAL CENTER (PHILADELPHIA).—A \$211,000 Federal grant from the National Institute of Mental Health to support an expanding teaching program for Fellows in psychiatry during the next 5 years has been awarded to Albert Einstein Medical Center. The award marks the increasing Federal recognition of the growing importance of selected general hospitals in training of psychiatrists and treating mental patients.

To be eligible for a Fellowship, a doctor must have completed at least his first year of psychiatric residency and training in basic psychiatry including descriptive psychiatry, psychopathology, genetics, history taking, case reporting, principles of therapy and practice of psychological testing, and social work.

RESEARCH TRAINING IN PSYCHIATRY.—The Graduate Educational Program of the State University of New York Downstate Medical Center offers a 2-year program of research training in psychiatry leading to the degree of Doctor of Medical Science. The program is open to M.D.'s who have completed 3 years of residency training in psychiatry. Candidates will also be accepted after 2 years of residency training, when the final

year of residency will be taken at the psychiatric division of Kings County Hospital, concurrently with this program.

A broad interdisciplinary faculty is responsible for teaching courses and for supervising research of candidates. Each candidate who is accepted will be granted a fellowship of \$7,500 for the first and \$8,000 for the second post-residency year. Three-year candidates will also receive \$7,100 for the final residency year. Applications for the academic year beginning September 1960 should be submitted before January 1, 1960. For further information write to Office of Admissions, Downstate Medical Center, 450 Clarkson Ave., Brooklyn 3, N. Y.

THE LANGLEY PORTER NEUROPSYCHIATRIC INSTITUTE.—This San Francisco facility opened a 4-story annex in July, 1959. This million dollar structure, financed by the State of California and a \$150,000 Health Research Facilities grant from the U. S. Public Health Service, provides for expanded programs in psychiatric training and research. The first and second floors contain a new medical library, enlarged neuropathologic laboratories, conference rooms and service quarters. The third floor, devoted entirely to mental health research, has laboratories for biochemistry, physiology, and pharmacology, and quarters for the study of animal behavior as well as for research with human subjects. On the fourth floor a 12-bed neuropsychiatric unit gives the departments of psychiatry, neurology and neurosurgery facilities for cooperative research, and a 14-bed unit, for research in primarily psychiatric fields. The total bed capacity of the Institute is thus increased to 118. Formal dedication ceremonies will be held within the year.

EASTERN PSYCHIATRIC RESEARCH ASSOC., INC.—The fourth annual meeting of the Association will be held Friday and Saturday, October 23 and 24, 1959, at the Waldorf-Astoria Hotel, New York City. Morning and afternoon sessions will be held on

both days. A considerable range of new work will be reported.

On Friday afternoon there will be a panel discussion on "Neuropsychiatric Aspects of Space Medicine."

For further information address the Association at 40 Fifth Ave., New York, N. Y.

NORTH SHORE HOSPITAL LECTURES.—The opening lecture of the tenth annual lecture series on "Office Management of Emotional Disorders" will be held at the North Shore Hospital, 225 Sheridan Rd., Winnetka, Ill., Wednesday, October 7 at 8:00 p.m. Speaker: Dr. John I. Nurnberger. Topic: Diagnostic Signs and Symptoms of Emotional Disorders.

These lectures are approved by the American Academy of General Practice for post-graduate credit. For further information write to Samuel Liebman, M.D., Medical Director, North Shore Hospital, 225 Sheridan Rd., Winnetka, Ill.

CEREBRAL PALSY RESEARCH AND TRAINING GRANTS.—The United Cerebral Palsy Research and Education Foundation has funds available for grants for research and training, post doctoral fellowships in brain research, clinical fellowships in cerebral palsy including medical student fellowships. The next deadline for submission of application is March 15, 1960. For information address the: Director of Research, United Cerebral Palsy Research and Education Foundation, 321 West 44th Street, New York 36, New York.

DR. KANNER VISITING PROFESSOR UNIVERSITY OF MINNESOTA.—Dr. Leo Kanner who, in June 1959, retired as Professor and head of the Department of Child Psychiatry at the Johns Hopkins University School of Medicine, will spend the academic year, September 1959 to June 1960, at the Medical School of the University of Minnesota in the capacity of "distinguished visiting professor."

Dr. Kanner will be concerned with both under- and post-graduate training programs, occupying the position of Dr. Reynold Jensen, Director of the Division of

Child Psychiatry, who will be spending a sabbatical year in Europe.

OFFICE OF MENTAL RETARDATION, NEW YORK STATE.—The organization of this special office in the New York State Department of Mental Hygiene has been announced by Commissioner Paul H. Hoch, with the purpose of coordinating and developing all services for the mentally retarded under the department.

The state's six institutions for the mentally defective will be visited regularly and primary emphasis will be on improving care of patients, improving training programs, and facilitating placement of suitable patients in the community.

Dr. Arthur W. Pense, Deputy Commissioner, will be in charge of the new office at Albany.

REISS-DAVIS CLINIC FOR CHILD GUIDANCE.—The clinic will hold its Sixth Annual Institute of Child Psychiatry on November 7, 1959, at the Beverly Hilton Hotel. This meeting is offered to pediatricians and general practitioners in the Southern California area. Program this year will emphasize clinical case presentations. Further information can be obtained by writing to the Reiss-Davis Clinic for Child Guidance, 715 North Fairfax Avenue, Los Angeles 46, Calif.

DR. FREEMAN HONORED.—Word has been received that the Royal Medico-Psychological Association of Great Britain has recently elected Dr. Walter Freeman of Los Altos, California, to corresponding membership.

LEGAL ENVIRONMENT OF MEDICAL SCIENCE.—A report on the National Conference on the Legal Environment of Medical Science sponsored by the National Society for Medical Research at the University of Chicago, May 27-28, 1959, has been issued as a separate booklet.

The conference was divided into three sections: Section I includes a contribution dealing with the anatomical law, authorization for autopsies, the willing of bodies, etc.

Section II deals with animal experimentation, the responsibility of both suppliers

multiplicity of etiological agents there is a monotony of lesional mechanism and tissular reaction. Subsequently are considered treatment of cerebrovascular accidents, epilepsies, neurosyphilis, encephalitides, neurological syndromes with extrapyramidal dominance, multiple sclerosis and allied states, myopathies and myotonia, cerebro-spinal traumatism, neuralgias and peripheral nerve disorders, migraine and vertigos, meningitides, neurological aspects of alcoholics, barbiturate intoxication and finally disorders of sleep.

All the above subjects are presented in a systematic, finely classified way in the best French clinical tradition. There is a concise historical consideration of each topic, followed by clinical and etio-pathogenic classifications and descriptions of therapeutic measures accordingly.

Actual case material is presented succinctly. The sections on neurosyphilis, syndromes with extrapyramidal predominance, neuralgias and neurological problems of alcoholism are particularly well presented.

The neurological section ends appropriately in a discussion of disorders of sleep, and a general introduction to psychiatric treatment. The authors' point of view in this connection is explicitly "eclectic" including organic as well as psychodynamic considerations. The latter is evident in the authors' dealing with neuroses, where they briefly outline different psychotherapeutic approaches. The psychiatric section is divided into 14 chapters dealing with different therapeutic regimens applicable to different psychiatric syndromes, which are categorized in conformity with the present French classification. Somatic treatment of psychoses is extensively discussed: shock therapies, recent pharmacotherapies and sleep treatment. Unfortunately the discussion of the psychotherapy of psychoses is quite brief. The book ends with 2 long chapters on electro-radiotherapies of neurological disorders, which involve the use of different currents, i.e. faradic, galvanic, infra-red, ultra-violet, Roentgen and radio-active waves.

As a whole the book's excellence remains in the neurological section and in those aspects of psychiatric treatment with the predominance of somatic considerations. However, the meager attempt at psychological and psychodynamic formulations does not detract from the exceedingly detailed and clear way of this excellently organized book, which as a comprehensive text book of neuro-psychiatric treatment is unique.

EGO STRUCTURE IN PARANOID SCHIZOPHRENIA.

By *Luise J. Zucker, Ph.D.* (Springfield, Ill.: Charles C Thomas, 1958. \$5.50.)

Sixty paranoid schizophrenic patients were studied by use of Rorschach protocols, the Mosaic Test and Figure Drawings. The group was equally divided by sex. Half of the patients were ambulatory and the other half hospitalized. The following categories of response were scrutinized: contaminated responses, fluid contours, extension of the ego-field into other fields, sensitivity to external stimulus and disturbed body image.

Significant differences were found between ambulatory and hospitalized schizophrenics. The ambulatory schizophrenic displayed more conspicuous deviations in the area of bizarre, arbitrary and autistic thinking, especially in the sexual sphere, whereas the hospitalized schizophrenic showed more collapse of ego boundaries and practically no sexual responses. The ambulatory patient had a variety of defenses which appeared to fulfill adjustment needs. The hospitalized patient had a lack of defenses and paucity of phantasy life.

The study has practical implications in that it gives insight into the diagnosis of schizophrenia, makes distinctions between its benign and malignant forms and gives clues about the prognosis with psychotherapy. Provocative questions are raised in regard to therapeutic objectives and results. For example, it is postulated that phantasy is indicative of inner resources and represents a valuable defense which may be disturbed by psychotherapy and lead to further personality disruptions because of the patient's incapacity to deal with environmental events and interpersonal relationships.

This monograph is a valuable contribution to our knowledge of the fluidity of ego boundaries and the understanding of the psychopathology of different groups of paranoid schizophrenics. It is worth the attention of psychiatrists and psychologists interested in the theoretical and clinical aspects of the nature of schizophrenia.

HERBERT S. RIPLEY, M.D.,

Seattle, Wash.

A PSYCHIATRIST SPEAKS. Dr. C. Charles Burlingame. (Limited edition, privately printed for Mrs. C. Charles Burlingame by Connecticut Printers, Inc., 1959.)

This collection of representative selections from the writings and addresses of Dr. Burlingame-Burley to all his friends—may be regarded as the psychiatric will and testament of

one of the most advanced thinkers, planners and doers of our time in the field of mental health and illness. It was undertaken by Mrs. Burlingame only after she had received numerous requests from medical historians and colleagues for an authoritative statement of her husband's achievements and of the scientific views he held good. He traveled the world—he held two stars from the Airlines Hundred Thousand Miles Club—and shared data and experience with psychiatrists on five continents. He was decorated by the French and Polish governments and was an officer in the *Legion d'Honneur*. Perhaps his greatest organizational accomplishment was the detailed plans he drew up for the first great medical center in the country whereby as executive officer of the Joint Administrative Board for both Columbia University and Presbyterian Hospital he united these two great institutions in a centralized unit, the Columbia University Presbyterian Hospital Medical Center, a truly gigantic task brilliantly performed.

Dr. John I. Nurnberger, chairman of the department of psychiatry, Indiana University Medical School, and for a number of years director of residency training and of the laboratory at the Institute of Living, pays, in his foreword, warm tribute to his former chief whose pattern he emulates in his own professional career. Dr. Burlingame, he states, "was a confirmed organicist who believed, until his last day, that the secrets of the major psychiatric disturbances . . . would be revealed through structural, biochemical and neurophysiological channels," and while "he looked askance at psychoanalytically oriented psychotherapy . . . physicians competent in psychotherapeutic techniques who worked on his staff were quietly and enthusiastically supported by him directly and indirectly through his highly skilled management of the family and the friends of patients." And Dr. Nurnberger continues: "It is doubtful that any hospital of this type anywhere in the world could reflect a truly broad-spectrum eclectic program with equal skill and representation in all therapeutic disciplines."

Of great interest and value is the biographical sketch contributed by Arline Boucher Tahan. It is written with sympathetic insight and reveals the man in his enthusiasm, his tolerance, his kindness, his patience and impatience, his enormous capacity for work.

In 1931 he took over the venerable Hartford Retreat which he transformed into the Institute of Living and made it live up to its new name. Here he introduced his famed "educational therapy." Offices were opened in New York

and Boston and the interests of the Institute were served by its director being available each week for consultation in those two cities.

It may not be generally remembered that Burlingame was the first industrial psychiatrist in the United States. This phase of his career began in 1916 when he organized this new branch of industrial medicine for the manufacturing firm of Cheney Brothers of Manchester, Connecticut.

One of his most notable contributions to medicine as a whole was his arrangement with the American Medical Association in 1949 for incorporating in the programs of the annual meetings of that body a special session devoted exclusively to psychiatry and neurology. Burlingame was mainly responsible for organizing this 1949 program with the view to bringing to the attention of the general practitioner the essentials of these special fields, shorn of confusing terminology. The proceedings of this inaugural session, which took place only 6 months before his death, were published posthumously in a book titled *Neurology and Psychiatry in General Practice* and dedicated to Burlingame who had inspired it. These special programs have since been a regular feature of the transactions of the A.M.A. each year.

Burlingame was a notable pioneer in modern psychiatry and his views as presented in this book ranged over all departments of the subject and introduced numerous innovations worth following. His psychiatry was comprehensive and rooted in common sense. Education and re-education constituted the core of his therapy. For what is called "progressive" education he had little use, "because it has encouraged surface education, emotional irresponsibility, and exaggerated self-expression." The essence of psychotherapy, whatever its form, he defined as "personal tutoring in the art of living."

Recognizing that the bounds of psychiatry have been so stretched by both insiders and outsiders that one might almost say, with tongue in cheek, *nihil humani a psychiatria alienum*; Burlingame suggested that "it might be well to substitute the term psychological medicine for psychiatry, in order to disidentify this branch of medical practice from the flotsam and jetsam on the psychiatric sea."

Another important service to medical education rendered by Dr. Burlingame was the founding of the *Digest of Neurology and Psychiatry*, which abstracts month by month significant contributions from the periodical literature and from books. The *Digest* is sent free of charge to physicians and institutions throughout the world.

A special feature of the Institute is the splendidly equipped laboratory designed by Dr. Burlingame and which bears his name, and where active research is carried on.

Our gratitude to Ruth Parsons Burlingame for making this book available.

C.B.F.

SIGMUND FREUD AND THE JEWISH MYSTICAL TRADITION. By David Bakan. (Princeton, N. J.: D. Van Nostrand Co., 1958, pp. xix-328. \$5.50.)

Toward the better understanding of the origins of psychoanalysis we have recently had several valuable contributions—Jones' biography of Freud, The Fliess letters, Binswanger's and Martin Freud's books. To these may now be added Dr. Bakan's book which, I am sure, is destined to become a landmark in the study of the historical origins of psychoanalysis.

It is Dr. Bakan's thesis that psychoanalytic thinking, as expressed through the writings of Freud, owes its peculiar qualities principally to the fact that Freud had, as a Jew, learned to think in the traditionally Jewish mystical manner. Every Jew, whether he learns Hebrew or not, if he is brought up in a Jewish environment will inevitably absorb something of this mode of thinking, and it will remain with him all the years of his life. It is not an accident that the earliest and among the leading psychoanalysts of every country, men and women of Jewish cultural antecedents have played so prominent and brilliant a role.

The Jewish mystical tradition is essentially Kabbalistic, using this term in a general sense to mean not only the *traditional*, but also to cover most of those works which, like the *Zohar*, were designed to show the initiated how to extract the hidden meanings and mysteries from the Scriptures. The Kabbalistic tradition is pervaded by a sense of secrecy, mystery, and power.

Dr. Bakan, with great learning and much attention to detail, convincingly argues that Freud, in his thinking, is in the direct line of succession of the Kabbalists. Dr. Bakan's development of his thesis is a delight to follow, and I must say that I have not read as analytically enchanting a piece of research as this in years. It is quite beyond my powers to give any further account of the manner in which the author pinpoints his case without virtually reproducing his book, for like all good writers, Dr. Bakan says a maximum number of things in a minimum number of words. His book is brilliantly persuasive, and there is no doubt at all that he has written one of

the most fascinating and fundamental books on the origins of psychoanalysis that has thus far appeared.

If there is a criticism to be made it is that in his concentration upon the Jewish mystical tradition, though he has probed deeply, Dr. Bakan has not gone quite as far afield as he might have done in the Jewish tradition with reference to its influence upon Freud's thinking. Insufficient attention is paid to the *Talmud* and the *Gemorrhah*. Freud, as Dr. Bakan is well aware, in childhood had been exposed to the teaching of the Scriptures in Hebrew. This being so he could scarcely have avoided some knowledge of the existence of these works and what they dealt with. In any event, Jews are always telling stories from these works and quoting from them, as they do from the great commentators on them like Rashi or Rumbum, and others. Whether Freud heard these stories and the jokes derived from these sources in German or Yiddish is of no great moment. *Wit and the Unconscious* bears sufficient testimony to the fact that Freud didn't miss a word.

As anyone who has ever heard the *Talmud* or the *Gemorrhah* expounded by a learned Jewish commentator will know, Aristotelian or Millsian logic looks pretty pallid in comparison. The Principle of Excluded Middle, for example, simply has no existence in this mode of thought, for things *can* be and indeed *are* both A and *not-A* at one and the same time, and overt acts and statements can actually mean their contraries or contradictories, and so on. The subtlety of this kind of thinking can only be appreciated to the full by one who happens to be in the midst of it while he is at the same time studying logic and scientific method!

Every individual who is by culture a Jew is, to some extent, the heritor of this fine tradition in which he is early conditioned, and anyone at all familiar with that tradition who reads Freud can surely not have the least doubt that he was powerfully influenced by it. If there are any doubters, they should read Dr. Bakan's admirable book—but even if agreement is complete, they should read his book, anyway. It is a highly rewarding experience.

ASHLEY MONTAGU, Ph.D.,
Princeton, N. J.

ALCOHOL AND THE JEWS. By Charles R. Snyder. (New Haven: Yale Center of Alcoholic Studies, 1958, pp. 226. \$5.00.)

This book, subtitled "A Cultural Study of Drinking and Sobriety" and based on the author's doctoral dissertation, is Monograph No. 1 of the Yale Center of Alcohol Studies.

The purpose of these studies is to investigate

the problem of group differences in rates of drinking pathologies with the idea that known differences are not wholly explained by genetic and physiologic factors. The Jewish group was chosen as especially suitable for study because of its consistently low rate of drinking pathologies within a high incidence of drinking.

The author reports what happens to each group who drink rather than taking the entire group including abstainers. He stressed the fact that the Jew is brought up in a culture and religion which expects and approves of his drinking in moderation. The Roman Catholic and a very few Protestant groups (Church of England) have much the same attitude.

A great many tables with studies of the social and religious backgrounds of various groups of Jews, Catholics, and Protestants are given. The conclusions that seem to stand out are that there are fewer Jewish abstainers than there are Catholic and Protestant and that the more orthodox a person is in his religion, whether Jewish, Catholic, or Protestant, the less likely he is to drink excessively.

Among those who do drink, the Orthodox Jews are found to have the lowest degree of drunkenness; the Jewish Conservative group have a higher rate; the Jewish Reform a still higher rate; and the Jewish Secular the highest rate. Some evidence shows that among the Irish Catholics, intoxication varies inversely with participation in their religious activities. Among the Protestant groups, those who do drink have a higher percentage of drunkenness than do Jews and Catholics.

In a study of college students, the percentages of drinkers in each group who have been drunk over 5 times are: Jewish affiliated 4%, Italian Catholics 10%, Irish Catholics 13%, Methodist (white) 16%, Baptist (white) 15%, and Mormon 21%. The author states, "Mormons and other ascetic Protestant groups divorce the act of drinking entirely from the contexts and symbolism which are primary sources of social control (e.g., family, church, and religious community)." This would seem to indicate that in a group like the Mormons, where not only drinking alcohol but drinking coffee and tea and smoking tobacco are strictly forbidden, the individual who drinks at all has evidently broken away from his religious group. This in itself will stir up emotional problems and the individual therefore is more likely to go on to excessive drinking once he starts drinking, whereas in the Jew, whose drinking occurs under religious and family sanctions from a very early age, no such feelings are connected with the act of drinking itself.

The conclusions in this book are interesting and seem to be fairly well documented, but the material is poorly organized. The theories and other supporting data are mixed in with the examination of the data on the groups. There are no chapter summaries nor are conclusions drawn about various sections of the study. The results of the entire study are rather poorly summarized in about half a page at the end of the book. This is too bad since it may discourage some readers from wading through the entire book, which presents quite significant and important material.

K. M. B.

SCHIZOPHRENIA. By *Manfred Sakel* (New York: Philosophical Library, 1958, pp. 335. \$5.00.)

In the Foreword of this posthumously published book, Dr. Hans Hoff, present Head of the Department of Neurology and Psychiatry at the University of Vienna, where Dr. Sakel once worked in developing his method, writes "Manfred Sakel's introduction of insulin shock therapy for schizophrenia in 1927 was a milestone in the advancement of psychiatry." Most psychiatrists today will agree with this statement.

For many years schizophrenia has been designated as the most outstanding problem in mental hospitals and psychiatric practice, and its therapeutic history is filled with scores of methods of treatment that were once supported enthusiastically by groups of workers, only to be discarded later as inadequate.

The insulin coma method was unique in approach and rather startling in the favorable changes it was able to produce in certain selected schizophrenic patients. Following his graduation in medicine from the University of Vienna in 1925 Dr. Sakel made his first use of insulin to calm alcoholics and drug addicts at the Lichtenfelde Hospital in Berlin. Later (1933) the opportunity to experiment with schizophrenics was afforded him by Professor Otto Poetzl of the Vienna Clinic. These early findings with the procedure were presented in a lecture at the Academy of Science in Vienna which was published in *Wiener Klinische Wochenschrift* in 1933. This was published also in English in the *American Journal of Psychiatry* in 1937 (Vol. 93, p. 829). It is unnecessary here to trace the subsequent history of the world wide application of the insulin therapy, its various modifications and results, or to emphasize, particularly, its stimulating effect in encouraging many workers to experiment with other chemical and physical therapies. The details and the results of these

IN MEMORIAM

JACOB E. FINESINGER, M.D.

1902-1959

Jacob E. Finesinger died on June 19, 1959. At the age of 57 his already significant career was still in the process of development. He was one of the first generation of American professors of psychiatry who, while thoroughly familiar with the academic disciplines, are also trained in and conversant with psychoanalysis. In his search for truth and unifying principles, his approach was eclectic. He was fascinated by the light that the great figures in philosophy, the arts and the humanities threw upon the mysteries of human behavior; he was also acutely conscious of the importance of scientific method in arriving at valid and reliable insights. One early source of inspiration was his most admired teacher and a man of whom he spoke with feeling, H. S. Jennings, the geneticist. His debt to the father of psychoanalysis was often acknowledged with the wry comment about a colleague who seemed to have missed the point: "We can't all be Freud!" This comment reflected his characteristic impatience with intellectual mediocrity. Completely undogmatic, he maintained a questioning attitude, avoiding "closure" in discussions with colleagues and students; a favorite expression was "lets talk about it," and he loved to do just that. The breadth of his understanding, his constant pursuit of knowledge, his appreciation of the importance of investigation, and his pleasure in teaching marked him as a professor in the best sense of the word.

The son of a Rabbi, Jake, as his friends came to know him, revealed his strong identification with his background and his rich cultural heritage. Yet in his mature years, he avoided religious participation and placed his faith in rational thinking. Although he was always deeply interested in and moved by the arts, he was attracted to science at an early age. This combination of artistic and scientific interests was reflected in a series of exhibits of abstract

impressionist painting which he arranged at The Psychiatric Institute in Baltimore as part of a study of the creative process.

Dr. Finesinger was educated at The Johns Hopkins University where he received his bachelor of arts degree in 1923, a master's degree in zoology in 1925 and his medical degree in 1929. After an internship and residency in neurology at the Boston City Hospital, he pursued graduate training in psychiatry at the Boston Psychopathic Hospital. The early 1930's saw him studying psychoanalysis in Vienna and conditioned responses in Pavlov's Russian laboratory. His early stay in Vienna was very meaningful to him and he often spoke of it, particularly after his first return visit in 1957. Later, he continued his psychoanalytic training in Boston. During this period he also began his academic career at the Harvard Medical School and the Massachusetts General Hospital where he remained on the faculty, in Stanley Cobb's Department, directing the clinical psychiatric service until 1949. His research was wide ranging, encompassing physiological as well as psychological and psychiatric problems, but he gradually began to focus up in the development of systematic, rational principles of psychotherapy and interviewing technique, a subject that was to occupy him for the rest of his professional life. One of the movies of interviewing technique which he made under the sponsorship of the Veterans Administration is a classic which is widely used for teaching non-psychiatric physicians as well as resident psychiatrists.

It took much thought and some courage for Jake to uproot himself and his family from their beloved Boston for a return to the Baltimore of his youth. The transition was accomplished, however, and he came to the University of Maryland as Professor and Head of the Department of Psychiatry in 1950. In late 1952 the doors of the Psychiatric Institute of the University were opened, and he became its first Director.

Here he began to translate into reality his concept of a broad multidisciplinary approach to the problems of human behavior and he was successful in establishing an Institute in which, under one roof, the attempt to understand mental life was pursued in terms ranging from those of the neurochemist concerned with synaptic transmission, to those of the philosopher concerned with logic, morality and values. At the same time it was necessary to organize the clinical services, a training program for residents, and teaching for undergraduate medical students. It is perhaps in this last area, that of undergraduate teaching, that Jake found his greatest professional satisfactions in Baltimore. A friend and colleague of long-standing, who observed him teaching the freshman and sophomore classes some months after his illness was known, commented on the power of his communication with the students. The personal impact of his intellectual and professional message was conveyed, he said, "with all of the pungent, bittersweet flavor that was Jake." Under the Finesinger influence the medical curriculum at Maryland was broadened to grant psychiatry new importance during all four of the undergraduate years. True to form, he also initiated a research program investigating the teaching and learning process.

The community responsibilities of the academic physician in this age are heavy. Jake devoted much needed time and energy to a host of advisory boards and committees dealing with social and psychiatric problems in the Baltimore area. On the national level, in addition to membership in many professional societies, he served as consultant in psychiatry to the Veterans Administration and to the U. S. Army, and was a member of the Committee on Veterans

Medical Problems and that on psychiatry of the National Research Council. In his work with the army he was instrumental in organizing and directing a series of courses in psychotherapeutic medicine for military personnel. During the war he did research on aircraft pilot selection, served as executive for the Port of Boston, as a consultant in neuropsychiatry for the U. S. Public Health Service, and as a member of the Medical Advisory Board of the Selective Service System. An honor which gave him particular pleasure was his appointment in January 1958 as Editor-in-Chief of *The Journal of Nervous and Mental Diseases*.

One measure of a man is the manner in which he meets his final illness. Jake lived for thirteen months following an operation which revealed the inevitable prognosis. During this time and even during the final weeks of hospitalization, he revealed a personal courage and consistent concern with the well-being of those around him which continued his influence as a teacher to the last.

He is survived by his wife, the former Grace Lubin, who has shared his interests, and by his children to whom he transmitted a respect and an appreciation for the things which he, himself, considered important. His son, Joe L. Finesinger, is a medical student at Western Reserve and his daughter, Ruth, is married to Dr. Sheppard Kellam, one of his former students, who is now in his final phase of training in psychiatry and engaged in research in neuropharmacology. In addition he leaves two brothers, Dr. Abraham L. Finesinger and Dr. Solomon B. Finesinger, and his sister, Mrs. Irving Blank.

Eugene B. Brody, M.D.,
Baltimore, Md.

PSYCHIATRIC EVALUATION OF CANDIDATES FOR SPACE FLIGHT¹

GEORGE E. RUFF, CAPT., USAF(MC), AND EDWIN Z. LEVY, CAPT., USAF(MC)²

The high levels of stress expected in space flight require careful screening of potential pilots by psychological and physiological techniques. Since emotional demands may be severe, special emphasis must be placed on psychiatric evaluation of each candidate for a space mission.

The selection process begins with a detailed analysis of both the pilot's duties and the conditions under which he will carry them out. As long as we have had no direct experience with space flight, some aspects of this analysis will necessarily be speculative. We must thus rely heavily on knowledge of behavior during stress situations in the past. As a result, data from military operations, survival experiences and laboratory experiments have guided the choice of men for space missions now being planned.

After the requirements of the mission and the qualifications of the individual best suited to accomplish it have been decided, it is necessary to select measures for determining who has the most of each desirable characteristic and the least of each undesirable characteristic. This can be done by using interviews and projective tests to give an intensive picture of each individual. Objective tests supplement the personality evaluation and measure intellectual functions, aptitudes and achievements. After examination of the background data, interview material and test results, clinical judgment is used to decide which men are psychologically best qualified for the assignment.

As first-hand knowledge of space flight increases, these procedures must be re-examined. When enough data have accumulated, predictions can be checked against

performance criteria. Methods which predicted accurately will be retained and improved. Those with little value will be discarded. New measures can be added on the basis of increasing experience. Once correlations between psychological variables and the quality of performance have been determined, the accuracy of future selection programs should be raised.

A clinical approach of this type was used in selecting pilots for the first U. S. manned satellite experiment—Project Mercury. The objective was to choose men for a two-year training program, followed by a series of ballistic and orbital flights. The pilot's duties will consist largely of reading instruments and recording observations. However, he will retain certain decision-making functions, and will be required to adapt to changing conditions as circumstances may demand.

By combining data on the nature of this mission with information on behavior during other stressful operations, the following general requirements were established:

1. Candidates should have a high level of general intelligence, with abilities to interpret instruments, perceive mathematical relationships and maintain spatial orientation.
2. There should be evidence of sufficient drive and creativity to insure positive contributions to the development of the vehicle and other aspects of the project as a whole.
3. Relative freedom from conflict and anxiety is desirable. Exaggerated and stereotyped defenses should be avoided.
4. Candidates should not be over-dependent on others for the satisfaction of their needs. At the same time, they must be able to accept dependence on others when required for the success of the mission. They must be able to tolerate either close associations or extreme isolation.

¹ Read at the 115th annual meeting of The American Psychiatric Association, Philadelphia, Pa., Apr. 27-May 1, 1959.

² Stress & Fatigue Section, Biophysics Branch, Aerospace Medical Laboratory, Wright-Patterson Air Force Base, Ohio.

5. The pilot should be able to function when out of familiar surroundings and when usual patterns of behavior are impossible.
6. Candidates must show evidence of ability to respond predictably to foreseeable situations, without losing the capacity to adapt flexibly to circumstances which cannot be foreseen.
7. Motivation should depend primarily on interest in the mission rather than on exaggerated needs for personal accomplishment. Self-destructive wishes and attempts to compensate for identity problems or feelings of inadequacy are undesirable.
8. There should be no evidence of impulsiveness. The pilot must act when action is appropriate, but refrain from action when inactivity is appropriate. He must be able to tolerate stress situations passively, without requiring motor activity to dissipate anxiety.

The chances of finding men to meet these requirements were increased by the preselection process. Eligibility for the mission was restricted to test pilots who had repeatedly demonstrated their ability to perform functions essential for the Mercury project. Records of men in this category were reviewed to find those best suited for the specific demands of the mission. A group of 69 were then invited to volunteer. The 55 who accepted were given a series of interviews and psychological tests. On the basis of these data 32 were chosen for the final phase of the selection program. This phase was designed to evaluate each candidate's medical and psychological status, as well as to determine his capacity for tolerating stress conditions expected in space flight.

The psychological evaluation included 30 hours of psychiatric interviews, psychological tests and observations of stress experiments. The information obtained was used to rate candidates on a 10-point scale for each of 17 categories. Ratings were made on the basis of specific features of behavior—both as indicated by the past history and as observed during the interviews. Even though the general population was used as a reference group, the scales are normative only in an arbitrary sense.

The 10 levels represent subjective decisions on which characteristics are ideal, which are average and which are undesirable. Although the reliability among raters is excellent, validation studies have not yet been done.

The categories are:

1. *Drive*—An estimate of the total quantity of instinctual energy.
2. *Freedom from conflict and anxiety*—A clinical evaluation of the number and severity of unresolved problem areas and of the extent to which they interfere with the candidate's functioning.
3. *Effectiveness of defenses*—How efficient are the ego defenses? Are they flexible and adaptive or rigid and inappropriate? Will the mission deprive the candidate of elements necessary for the integrity of his defensive system?
4. *Free energy*—What is the quantity of neutral energy? Are defenses so expensive to maintain that nothing is left for creative activity? How large is the "conflict-free sphere of the ego?"
5. *Identity*—How well has the candidate established a concept of himself and his relationship to the rest of the world?
6. *Object relationships*—Does he have the capacity to form genuine object relationships? Can he withdraw object cathexes when necessary? To what extent is he involved in his relationships with others?
7. *Reality testing*—Does the subject have a relatively undistorted view of his environment? Have his life experiences been broad enough to allow a sophisticated appraisal of the world? Does his view of the mission represent fantasy or reality?
8. *Dependency*—How much must the candidate rely on others? How well does he accept dependency needs? Is separation anxiety likely to interfere with his conduct of the mission?
9. *Adaptability*—How well does he adapt to changing circumstances? What is the range of conditions under which he can function? What are the adjustments he can make? Can he compromise flexibly?
10. *Freedom from impulsivity*—How well can the candidate delay gratification of

his needs? Has his behavior in the past been consistent and predictable?

11. *Need for activity*—What is the minimum degree of motor activity required? Can he tolerate enforced passivity?
12. *Somatization*—Can the candidate be expected to develop physical symptoms while under stress? How aware is he of his own body?
13. *Quantity of motivation*—How strongly does he want to participate in the mission? Are there conflicts between motives—whether conscious or unconscious? Will his motivation remain at a high level?
14. *Quality of motivation*—Is the subject motivated by a desire for narcissistic gratification? Does he show evidence of self-destructive wishes? Is he attempting to test adolescent fantasies of invulnerability?
15. *Frustration tolerance*—What will be the result of failure to reach established goals? What behavior can be expected in the face of annoyances, delays or disappointments?
16. *Social relationships*—How well does the subject work with a group? Does he have significant authority problems? Will he contribute to the success of missions for which he is not chosen as pilot? How well do other candidates like him?
17. *Overall rating*—An estimate of the subject's suitability for the mission. This is based upon interviews, test results and other information considered relevant.

It can be seen that categories 1, 2, 4 and 10 are largely economic constructs; 3, 5, 6 and 7 are ego functions; while the rest are specific characteristics considered important for space flight. The categories represent many different levels of abstraction and are not independent dimensions. In the final analysis, they are less a means of quantifying data than of organizing their interpretation. Not only do they provide a method to compare one subject with another, but also tend to focus attention on the material most closely related to the mission requirements.

An initial evaluation of each man was

made by two psychiatrists, through separate interviews during the preliminary screening period. One interview was devoted primarily to a review of the history and current life adjustment, while the other was relatively unstructured. Finally, ratings were compared, information pooled and a combined rating made. Areas of doubt and disagreement were recorded for subsequent investigation.

The men accepted for the final screening procedure were seen again several weeks later, after an intensive evaluation of their physical status had been completed. Each candidate was reinterviewed and the following psychological tests were administered.

Measures of motivation and personality

1. Rorschach
2. Thematic Apperception Test
3. Draw-A-Person
4. Sentence Completion Test
5. Minnesota Multiphasic Personality Inventory
6. *Who Am I?*—The subject is asked to write 20 answers to the question, "Who Am I?" This is interpreted projectively to give information on identity and perception of social roles.
7. *Gordon Personal Profile*—An objective personality test yielding scores for "Ascendancy," "Responsibility," "Emotional Stability" and "Sociability."
8. *Edwards Personal Preference Schedule*—A forced-choice questionnaire measuring the strengths of Murray's needs.
9. *Shipley Personal Inventory*—Choices are made from 20 pairs of self-descriptive statements concerning psychosomatic problems.
10. *Outer-Inner Preferences*—A measure of interest in and dependence on social groups.
11. *Pensacola Z-Scale*—A test of the strength of "authoritarian" attitudes.
12. *Officer Effectiveness Inventory*—A measure of personality characteristics found in successful Air Force Officers.
13. *Peer Ratings*—Each candidate was asked to indicate which of the other members of the group who accompanied him through the program he liked best, which one he would like to accompany him on a two-man mission

and which one he would assign to the mission if he could not go himself.

Measures of intellectual functions and special aptitudes :

1. Wechsler Adult Intelligence Scale
2. Miller Analogies Test
3. Raven Progressive Matrices—A test of non-verbal concept formation.
4. Doppelt Mathematical Reasoning Test—A test of mathematical aptitudes.
5. Engineering Analogies—A measure of engineering achievement and aptitudes.
6. Mechanical Comprehension—A measure of mechanical aptitudes and ability to apply mechanical principles.
7. Air Force Officer Qualification Test—The portions used are measures of verbal and quantitative aptitudes.
8. Aviation Qualification Test (USN)—A measure of academic achievement.
9. Space Memory Test—A test of memory for location of objects in space.
10. Spatial Orientation—A measure of spatial visualization and orientation.
11. Gottschaldt Hidden Figures—A measure of ability to locate a specified form imbedded in a mass of irrelevant details.
12. Guilford-Zimmerman Spatial Visualization Test—A test of ability to visualize movement in space.

In addition to the interviews and tests, important information was obtained from the reactions of each candidate to a series of stress experiments simulating conditions expected during the mission. Neither the design of these tests nor the physiological variables measured will be discussed. Psychological data were derived from direct observation of behavior, post experimental interviews and administration before and after each run of alternate forms of 6 tests of perceptual and psychomotor functions. These procedures were :

1. *Pressure Suit Test*—After dressing in a tightly-fitting garment designed to apply pressure to the body during high altitude flight, each candidate entered a chamber from which air was evacuated to simulate an altitude of 65,000 feet. This produces severe physical discomfort and confinement.
2. *Isolation*—Each man was confined to a dark, soundproof room for 3 hours.

While this brief period is not stressful for most people, data are obtained on the style of adaptation to isolation. This procedure aids in identifying subjects who cannot tolerate enforced inactivity, enclosure in small spaces or absence of external stimuli.

3. *Complex Behavior Simulator*—The candidate was required to make different responses to each of 14 signals which appeared in random order at increasing rates of speed. Since the test produces a maximum of confusion and frustration, it measures ability to organize behavior and to maintain emotional equilibrium under stress.
4. *Acceleration*—The candidates were placed on the human centrifuge in various positions and subjected to different "g" loads. This procedure leads to anxiety, disorientation and blackout in susceptible subjects.
5. *Noise and vibration*—Candidates were vibrated at varying frequencies and amplitudes and subjected to high energy sound. Efficiency is often impaired under these conditions.
6. *Heat*—Each candidate spent 2 hours in a chamber maintained at 130°. Once again, this is an uncomfortable experience during which efficiency may be impaired.

After all tests were completed, an evaluation of each man was made by a conference of those who had gathered the psychological data. Final ratings were made in each category described previously, special aptitudes were considered, and a ranking within the group was derived. By combining the psychiatric evaluations, results of the physical examinations and physiological data from the stress test procedures, the group was subdivided under the headings, "Outstanding," "Recommended," and "Not Recommended." Finally, 7 men were chosen from the list according to the specific needs of the Mercury project.

IMPRESSIONS OF CANDIDATES FOR SPACE FLIGHT

Although the results of the selection program can't be assessed for several years, impressions derived from psychiatric evalu-

ations of these candidates are of interest. In answer to the question, "What kind of people volunteer to be fired into orbit?" one might expect strong intimations of psychopathology. The high incidence of emotional disorders in volunteers for laboratory experiments had much to do with the decision to consider only candidates with records of effective performance under difficult circumstances in the past. It was hoped that avoiding an open call for volunteers would reduce the number of unstable candidates.

In spite of the preselection process, we were surprised by the low incidence of such disorders in the 55 candidates who were interviewed. For the 31 candidates who survived the initial screening and physical examination, repeat interviews and psychological tests confirmed the original impressions. There was no evidence for a diagnosis of psychosis, clinically significant neurosis or personality disorder in any member of this group.

Certain general comments can be made concerning the 31 men who received the complete series of selection procedures. The mean age was 33, with a range from 27 to 38. All but one were married. Twenty were from the Midwest, Far West or Southwest. Only two had lived in large cities before entering college. Twenty-seven were from intact families. Twenty were only or eldest children. (In this connection, it is perhaps worth noting that 4 of the 7 men chosen are named "junior.") Pronounced identifications with one parent were about equally divided between fathers and mothers, although mothers with whom such identifications were present were strong, not infrequently masculine figures.

Impressions from the interviews were that these were comfortable, mature, well-integrated individuals. Ratings in all categories of the system used, consistently fell in the top third of the scale. Reality testing, adaptability and drive were particularly high. Little evidence was found of unresolved conflict sufficiently serious to interfere with functioning. Suggestions of overt anxiety were rare. Defenses were effective, tending to be obsessive-compulsive, but not to an exaggerated degree. Most were direct, action-oriented individuals, who spent

little time introspecting.

Although dependency needs were not over-strong, most showed the capacity to relate effectively to others. Interpersonal activities were characterized by knowledge of techniques for dealing with many kinds of people. They do not become over-involved with others, although relationships with their families are warm and stable.

Because of the possibility that extreme interest in high performance aircraft might be related to feelings of inadequacy in sexual or other areas, particular emphasis was placed on a review of each candidate's adolescence. Little information could be uncovered to justify the conclusion that unconscious problems of this kind were either more or less common than in other occupational groups.

A high proportion of these men apparently passed through adolescence in comfortable fashion. Most made excellent school and social adjustments. Many had been class presidents or showed other evidence of leadership.

Most candidates entered military life during World War II. Some demonstrated an unusual interest in flying from an early age, but most had about the same attitudes toward airplanes as other American boys. Many volunteered for flight training because it provided career advantages or appeared to be an interesting assignment.

Candidates described their feelings about flying in a variety of terms: "something out of the ordinary," "a challenge," "a chance to get above the hubbub," "a sense of freedom," "an opportunity to take responsibility." A few look upon flying as a means of proving themselves or of building confidence. Others consider it a "way for good men to show what they can do."

Although half the candidates volunteered for training as test pilots, the others were selected because of achievements in other assignments. Most view test flying as a chance to participate in the development of new aircraft. It enables them to combine their experience as pilots and engineers. Their profession is aviation and they want to be in the forefront of its progress. Danger is admitted, but de-emphasized—most feel nothing will happen to them. But this seems to be less a wishful fantasy than

a conviction that accidents can be avoided by knowledge and caution. They believe that risks are minimized by thorough planning and conservatism. Very few fit the popular concept of the daredevil test pilot.

Although attempts have been made to formulate the dynamics underlying the pursuit of this unusual occupation, generalizations are difficult to make. Motives vary widely. While it is clear that conscious reasons may be unrelated to unconscious determinants, the variation in conscious attitudes illustrates the impossibility of a single explanation for a career which has different meanings for different individuals. One man, for example, stated that he enjoys flight testing because it allows him to do things which are new and different. He enjoys flying the newest aircraft available—vehicles that most pilots will not see for several years. Another is an aeronautical engineer who is primarily interested in aircraft design. He looks upon a flight test much as the researcher views a laboratory experiment.

Reasons for volunteering for Project Mercury show a mixture of professionalism and love of adventure. Candidates are uniformly eager to be part of an undertaking of vast importance. On one hand, space flight is viewed as the next logical step in the progress of aviation. On the other, it represents a challenge. One man expressed the sentiments of the group by saying, "There aren't many new frontiers. This is a chance to be in on one of them." Other expressions included ; "a new dimension of flight," "a further stage in the flight envelope of the manned vehicle," "a chance to get your teeth into something big," "the sequel to the aviation age," "a contribution to human knowledge," "an opportunity for accomplishment," "the program of the future," "an interesting, exciting field," "a chance to be on the ground floor of the biggest thing man has ever done."

At the same time, most candidates were practical. They recognized that this project will benefit their careers. To some it is a chance to insure an interesting assignment. Most recognize the trend away from conventional manned aircraft and look upon the Mercury project as a means for getting into the midst of future developments. One

said, "we're the last of the horse cavalry. There aren't going to be many more new fighters. This is the next big step in aviation. I want to be part of it." Most are aware of the potential personal publicity and feel this would be pleasant—but "not an important reason for volunteering."

Although all candidates are eager to make the flight, it is not their only concern. Most want to participate in development of the vehicle and have an opportunity to advance their technical training. The orbital ride is partly looked upon as a chance to test an item of hardware they have helped develop. Risks are appreciated, but accepted. Most insist they will go only when the odds favor their return. No one is going up to die. They are attracted by the constructive rather than the destructive aspects of the mission.

Psychological tests of these 31 men indicate a high level of intellectual functioning. For example, the mean full-scale W.A.I.S. scores for the 7 who have been selected range from 130 to 141, with a mean of 135. The pattern is balanced, with consistently high scores on both verbal and performance subtests.

Projective measures suggest the same healthy adaptations seen in the interviews. Responses to the Rorschach, for example, were well organized. Although not overly rigid, they did not suggest much imagination and creativity. Aggressive impulses tended to be expressed in action rather than fantasy.

Behavior during the isolation and complex behavior simulator tests (which might be considered input-underload and input-overload situations) showed evidence of great adaptability. No candidate terminated isolation prematurely and none viewed it as a difficult experience. As might be expected for this brief exposure, no perceptual changes were reported. Fifteen subjects "programmed" their thinking in isolation. In 5 of these men, the attempt to organize thoughts was considered evidence of an overly strong need for structuring. Sixteen permitted random thought, relaxed and enjoyed the experience. Most slept at least part of the time.

When placed under opposite conditions, with too much to do instead of too little,

the candidates were usually able to keep from falling hopelessly behind the machine. Only a few were troubled by the impossibility of making all responses promptly. The majority became content to do as well as possible, showing a gradually increasing level of skin resistance, even though working at a frantic pace.

Reactions to physiological stressors correlated positively with the psychiatric evaluations. Candidates who had been ranked highest on psychological variables tended to do best in acceleration, noise and vibration, heat, and pressure chamber runs. Their stress tolerance levels were among the highest of the hundreds of men subjected to these procedures in the past. Uncomplaining acceptance of the discomforts and inconveniences of this phase of the program appeared to reflect not only their strong motivation, but also their general maturity and capacity to withstand frustration.

In summary, it is suggested that the most

reasonable approach to selecting men for doing something no one has done before is to choose those who have been successful in demanding missions in the past. To decrease the probability of error, a broad sample of behavior must be observed. Every effort should be made to make these observations as relevant to the expected demands of the mission as possible.

By selecting only those candidates who were able to adapt to whatever conditions confronted them, we hope we have found those who are best qualified for space flight. Our confidence is further strengthened by the attitudes of the men who were chosen. Most reflected the opinion of the candidate who, when asked why he had volunteered, explained: "In the first 50 years since the Wright Brothers, we learned to fly faster than sound and higher than 50,000 feet. In another 5 years we doubled that. Now we're ready to go out 100 miles. How could anyone turn down a chance to be part of something like this?"

A GRAPHIC COMPARISON OF FIVE PHENOTHIAZINES

JACKSON A. SMITH, M.D.,¹ DOROTHY CHRISTIAN, R.N.,²
ELAINE MANSFIELD, R.N.,³ AND ALFREDO FIGAREDO, M.D.³

The rapidity with which new medications for the treatment of the mental ill are being made available requires some system of screening these compounds which will permit of an early conclusion as to their clinical effectiveness and toxicity. Ideally, such a screening procedure would be sufficiently standardized to allow of a clinical comparison of the effectiveness of compounds thought to have similar actions. This is a report of such a screening method and the result of its use in evaluating 5 different phenothiazine derivatives.⁴

METHOD

To compare the relative effectiveness of different compounds, it is necessary to standardize the patient group, methods of evaluating behavioral change, and the routine to be followed in administering the several drugs. To accomplish these ends, the following was carried out:

Pertinent data on 2,200 patients were tabulated on key-sort cards. This allows of a rapid selection of similar groups of patients in accord with the desired criteria. In the studies reported here, these criteria consisted of duration of hospitalization, age, willingness to take oral medication, and diagnosis.

The patient group was composed of chronic patients hospitalized a minimum of

one year. Diagnostically, all of those included were schizophrenic reactions with the exception of 3 who were classified as manic-depressive reactions.

The forms for recording behavioral change were standardized and included a modified mental status, an observation checklist, an activity chart, and progress notes described previously. The data recorded on these charts were in the form of observation or a verbatim recording of the patients' statements and not based on the judgment or opinion of the recorder. In each drug study the same psychiatric nurse made all the observations.

The routine followed in administering the products being evaluated was the same as that pursued in the ordinary medical treatment of the patient on the ward. No change in the personnel responsible for the patients' care was made and the patients remained on the wards where they had been previously housed.

Since the same or similar patients were treated with more than one compound and the criteria for determining behavioral change were standardized, the improvement and side effects noted are graphic.

The following descriptions are included for each compound: 1. The name of the preparation being tested. 2. The patient group. 3. Dosage. The dosage shown for each drug was increased uniformly at the indicated intervals, with these exceptions: (a) When side effects developed, the dosage was not increased, and if the side effects persisted the dose was reduced to the previous level or the drug was discontinued depending on the nature and severity of the side effect; and (b) If half of the patients developed side effects, no further increase in dosage was attempted.

SUMMARY

Five phenothiazine derivatives have been studied using similar groups of patients and similar methods of evaluating and recording behavioral change. All of the patients included in these reports had been hospitalized longer than one year and had

The following also supplied grants-in-aid: The Upjohn Company, The Squibb Institute for Medical Research, and Winthrop Laboratories. These studies were supported in part by the Nebraska Board of Control Fund for Psychiatric Research.

FACTORS INDICATING IMPROVEMENT

Improvement, minimal (+1):

Indication of a consistent though slight increase in 2 or more of the following:

- Participating in activities
- Socialization
- Interest in personal appearance
- Appropriate affect and speech
- Attention span, alertness
- "Feeling better" (patient's statement)
- Friendliness
- Cooperation
- Attempt to communicate

Decrease in:

- Agitation
- Tension
- Incontinence
- Overt Hostility

Improvement, marked (+2):

Definite and consistent increase in the criteria listed for minimal improvement, resulting in any or all of the following:

Marked improvement in behavior and appearance.

Delusions or hallucinations diminished and of less concern to the patient.

Spontaneous answers during interview with increased interest in surroundings.

FACTORS INDICATING SIDE EFFECTS

1. Leukopenia
2. Facial edema, skin rash
3. Tremor, loss of associated movements, muscular rigidity
4. Drooling, mask-like facies or dysphagia
5. Decrease in motor activity sufficient to interfere with participation in routine activities
6. Increased agitation with depression and somatic complaints
7. Marked hypotension, syncope
8. Nausea and vomiting
9. Marked pallor

RESULTS

The 5 preparations evaluated were:

1. SQ 4918 : 4-[3-[2-(trifluoromethyl)-10-phenothiazinyl] propyl]-1-piperazineethanol dihydrochloride (Vespazine)
2. Win-13, 645-5 : 8-[3-[10-(2-Chlorophenothiazinyl)] propyl]-3-hydroxynortropane ethanesulfonate
3. SC-7105 : 1-(2 acetoxylethyl)-4-[3-(2-chloro-10-phenothiazine) propyl] piperazine dihydrochloride (Dartal—Brand of thiopropazate dihydrochloride)
4. Adazine : 10-(3-dimethylaminopropyl)-2-(trifluoromethyl) phenothiazine hydrochloride
5. Sch-3940 : 1-(2-hydroxyethyl)-4-[3-(2-chloro-10-phenothiazyl)-propyl]-piperazine (perphenazine—Trilafon)

been refractory to previous treatment efforts.

The results indicate that this group of chronic patients, all but 3 of whom were schizophrenic, were no more responsive to these compounds than to treatment procedures earlier tried. The graphing of the data simplifies the comparison of compounds evaluated under similar conditions.

Improvement occurred so infrequently in these screening procedures that a controlled or "double-blind" study did not appear necessary.

SUICIDE IN ADOLESCENTS¹

BENJAMIN H. BALSER, M.D.,² AND JAMES F. MASTERSON, JR., M.D.³

The problem of suicide in adolescents has received little study. With the exception of Mason's report in 1954(10), on four cases of suicidal attempt in adolescents, no reports were found. There are a few reports on child suicide, but by far the great majority of studies have been done on adults. As a background for a general study of suicide in adolescents, pertinent points in the literature on both child and adult suicide will be presented.

REVIEW OF LITERATURE

Adult

Psychoanalytic.—Suicide has been customarily associated with the affective disorders, and the dynamics as indicated by Freud(4) and Abraham(5) in depression, that is, dependent ambivalence, guilt, oral incorporation, turning of the hostility against the self. However, Zilboorg stressed the point that no clinical entity is immune to suicidal drive(21), and that it is not possible to demonstrate the dynamics of depression as the only determining factor. He suggests the possibility that there is more predisposition to suicide where there is a history of death of a person close to the child during the phallic or pubertal period, especially if these events occur with a background of strong, constant stimulation of the child's attachment to one of the parents. He also suggests that suicide at puberty is a primitive, impulsive result of frustrated genital wishes rather than oral aggressive or spite wishes. Menninger describes the 3 elements to the suicidal drive (11), that is, the desire to kill, be killed, and to die. He also mentions the concept of partial suicide.

Clinical.—Studies have been done on both completed suicide and suicidal attempts. Jamieson in a study of 100 hospital cases of completed suicides found that 65% had been diagnosed as affective disorders and 15% schizophrenic and paranoid disorders (6). This would support the conclusion that in these adults who are emotionally disturbed and commit suicide the affective disorders play a predominant part. Sixty-seven percent of the patients had one or more previous suicidal attempts and 61% had a history of psychosis or suicide in the family. Several studies on suicidal attempts support the importance of the loss of a parent early in life. Palmer(12) and Reitman(13) each studied 25 cases of suicidal attempts and found that 68% had lost one or both parents before 14. Stengel(17) in 1942, in a follow-up study of 138 patients with suicidal attempts found only one death by suicide and concluded that suicide and suicidal attempts are separate groups, but that they overlap.

Weiss reports that suicide is more common in older age groups(19), single, divorced or widowed males, while suicidal attempts are more common in younger age groups, and in married women. In reviewing the statistics on suicide versus suicidal attempt, he concluded that many suicidal attempts are like Russian roulette with the lethal probability varying from certain survival to certain death, with an external force compelled to make the decision. Rubinstein, *et al*(14), in 1958, reported a study of 44 suicidal attempts seen in emergency, from the point of view of motivation, interpersonal communicative functions, and social effects. They concluded that in 36 of the cases, the patient was involved in struggles with persons important to him and that the suicidal attempt was self preservative, directed at mobilizing support and effective changes; that a continuum exists between this motivation and the directing of aggressive and destructive impulses toward the self and others. The 8 patients without desired social effects

¹ Read at the 115th annual meeting of The American Psychiatric Association, Philadelphia, Pa., Apr. 27-May 1, 1959.

² From the Department of Psychiatry, College of Physicians and Surgeons, Columbia University, and St. Luke's Hospital, New York, N. Y.

³ From the Department of Psychiatry, Cornell University Medical College and the New York Hospital (Payne Whitney Psychiatric Clinic).

were found to have more serious emotional illnesses.

Children

Suicide in children is rare, usually impulsive, and not particularly associated with depression and suicidal preoccupation. In statistical studies, no deaths are reported in children under 5, and the number of deaths in the United States in the 5-14 age group between 1930-1945 ranged between 39-59 per year(21). It would be very interesting to know how many of these deaths occurred between 12 and 14. The boy-girl ratio is 6:1. Despert reviewed 400 consecutive cases (ages 2-16) for depressive mood and/or suicidal preoccupation or suicidal attempt(3). She found 26, of whom only 5 had manifested intense suicidal preoccupations and gone through aborted suicidal attempts. The remaining 21 showed depressive mood without suicidal preoccupation or intent. She mentions that since child suicides are impulsive, they usually escape the attention of the psychiatrist. She concludes that depression and suicide are rare in children and do not have the close association assumed to exist in adults.

Schecter(15) gives a theoretical basis to Despert's(3) findings by stating that since the child is so dependent on the love object for gratification, and since the process of identification is not complete, the turning of hostility against the self is too frightening, thus, children rarely commit suicide, but express self-destructive feelings in other ways, *i.e.*, suicidal equivalents, depression, accidental injuries, antisocial acts.

Keeler in a study of 11 children's reactions to the death of a parent was able to demonstrate several findings(7). Depression, present in all 11, was highly correlated with presence of strong feelings toward the parent. Fantasies of reunion with the dead parent were present in 8, and identification with the dead parent in 7. Suicidal preoccupation and attempts in 6 seemed to represent identification with the deceased parent, a wish to be reunited, an attempt to escape an unbearable situation, and expression of aggression toward themselves.

Schilder and Wechsler observed that the child thinks about death as a kind of deprivation which is unbearable but seldom permanent(16). The child expects the destroyed object to return. Bender and Schilder concluded in another study(1), the child reacts to an unbearable situation with an attempt to escape. Mostly these unbearable situations consist of the deprivation of love which provokes aggressiveness against those who deny love. Under the influence of guilt these tendencies are turned against the self. The suicidal attempt constitutes a punishment against the environment, and an attempt to get a greater amount of love.

SUICIDE IN ADOLESCENTS

Mason reported 4 adolescent diabetics who used their illness as a mechanism for suicidal attempts(10); discussed the concept of partial suicide and questioned the relationship of incestuous preoccupations to suicide in adolescents. Bakwin(1) reports that suicide is the 5th cause of death in the 15-19 age group and represents 2.5% of all deaths in this group. The mortality per 100,000 varies considerably from country to country with Japan being the highest: 26.1 for boys and 18.7 for girls, and Ireland the lowest with 0.6 for boys and 1.1 for girls. The rate in the United States which is 4.6 for boys and 1.6 for girls has been steadily declining for the last 35 years.

To investigate the relative prevalence of the suicidal problem in adolescents, statistics were obtained both on completed suicide and on suicidal attempts (Fig. 1).

There are about 280-290 suicides in the adolescent age group (15-19) in a year in the United States. This number is only about 2% of the total, but it is 6 times higher than the 10-14 age group. It would be interesting to know how many in the 10-14 group are 13 or 14. At any rate, there is a sharp increase in completed suicide during adolescence as compared to childhood. The male-female ratio is 3:1, which is about half the ratio found in children.

Fig. 2 shows a review of two studies on suicidal attempts by Landrum(8) and Piker(9).

It has not been previously stressed that

FIG. 1

NUMBER OF COMPLETED SUICIDES PER YEAR BY AGE GROUP IN UNITED STATES(22)

Age	Year				
	1951	1952	1953	1954	1955
10-14	51	39	58	37	37
15-19	270	295	298	261	285
20-24	670	586	611	604	569
Over 24	14,918	14,647	14,980	15,654	15,864
Totals	15,909	15,567	15,947	16,556	16,755

FIG. 2

NUMBER OF SUICIDAL ATTEMPTS BY AGE GROUP

Age	Landrum(8)		Piker(9)	
10-14	5 (male = 1	female = 4)	15 (male = 4	female = 11)
15-19	122 (male = 11	female = 111)	223 (male = 24	female = 199)
20-24	239		409	
Over 24	634		1,170	
Totals	1,000		1,817	

suicidal attempts in adolescents represent such a large percentage of the total attempts, namely, 12%. There is a marked increase in attempts in the 15-19 group over the 10-14 group. This increase is many times greater than that which occurs in completed suicides. The increase occurs mostly in females who represent over 90% of the total. The female-male ratio was 10 : 1, the highest for any age group. The total of the female attempts was third highest, ranking only behind 20-24 and 25-29, while the male total was the lowest for any age group until the age of 65.

It would seem that the study of completed suicide alone gives a misleading picture of the total problem and that suicidal attempts, particularly in adolescent females are much more prevalent than they were thought to be.

The material reviewed raises many questions. What causes the female ratio for suicidal attempts to be so much higher than the male? Is there something in our culture that predisposes the female to use suicidal attempts in adolescence? Jamieson notes that depression and suicide have a close relationship in adults(6). Despert notes that depression and suicide do not have the same relationship in children(3). What is the relationship between suicide and affective disorders in adolescents?

Mason raised the question of the relationship of incestuous preoccupations to suicide (10). Could it be more present or more frustrated in females than in males? Zilboorg, Reitman, Palmer, Keller raise the question of the effect of death of a parent during childhood on later suicidal drive. Stengel, Weiss, Rubinstein postulate that successful suicide and suicidal attempts represent two different groups.

MATERIAL STUDIED

The goal of the present study was to investigate the total problem of the suicidal drive in adolescents. For this purpose 100 patients from the Payne Whitney Clinic Outpatient Department, 100 patients from private practice, and about 300 adolescent patients hospitalized at Payne Whitney Clinics were reviewed. The age range was 13-19 inclusive. Suicidal attempts were made by 3 in the private practice group, by 2 in the outpatient group and by 32 in the inpatient group, for a total of 37, of which 23 were diagnosed as schizophrenic; 4 of the 5 outpatients and 19/32 inpatients. This was such a striking finding that it was decided to concentrate this report on the relationship between schizophrenia and suicidal attempt in adolescents.

The psychopathology of the schizophrenic patients was primarily of the catatonic

and paranoid types. There was a clear delineation into acute and chronic types, and examples of both are given below :

Acute Schizophrenic Reaction.—H. H., a female, 18 years old, was admitted to the hospital 2 weeks after attempting suicide by jumping from a train. She was traveling home from college with a nurse because of depression and inability to concentrate and do work, despite adequate intelligence.

Diagnosis was schizophrenia, catatonic type. Patient was delusional, had auditory hallucinations, and spoke with inappropriate affect. She was preoccupied, mute, with muscular rigidity. She would not eat and was fed by tube for 8 weeks in the hospital. She was physically unkempt and had occasional urinary incontinence.

A month after hospitalization, patient was given subcoma insulin treatment. She still remained mute but became less resistant to treatment, although she made several attempts to escape through windows. Muscular rigidity, negativism, and feeding difficulties continued. Patient finally was transferred for chronic hospitalization.

Patient was a delicate child and a constant feeding problem, with many colds and allergic complaints. She studied unusually hard to achieve her good marks, competing with a most successful older brother and father. Patient was sensitive, stubborn, with body over-concern. There was a history of occasional depressed and tense periods with insomnia. Menses started at 13, were normal until onset of present illness, then stopped. Patient entered the college of her choice, but disliked her roommate and couldn't concentrate. She was referred to a psychiatrist who recommended that she be sent home.

Her father was a physician, domineering, and over-solicitous, who handled all the patient's physical problems, although he was strongly unsympathetic toward her mental illness. Patient felt this as rejection and showed passive resistance and some negativism toward him. Mother was a diabetic, shallow and unintelligent, who always preferred the brother to the patient.

Chronic Schizophrenic Reaction.—T. S., male, 17 years old, was admitted to hospital following a suicide attempt by ingestion of 110 sleeping tablets. Diagnosis was schizophrenic reaction. Patient discussed this suicide attempt in a very flattened, unemotional way, was confused, suspicious, delusional, and objected to group living. He felt he must die and

everyone else must die too. He had written 3 suicide notes in the previous year.

Patient was first seen at 13 in private psychiatric practice as an ambulatory patient. He was nervous, depressed, and had made suicidal threats. He complained of insomnia, and poor appetite. Despite a high I.Q. he was having academic difficulty and his school adjustment was bad, with no close friends.

His parents were divorced when patient was 9 and both remarried; his mother having 2 more children with her second husband. Patient respected his father with whom he lived after the divorce, but hated his very strict stepmother. His brother and sister were mentally ill. Paternal grandmother was hospitalized for depression and mental illness. A maternal uncle was alcoholic and suicidal. Patient was very fond of his mother with whom he could communicate and secure affection. He preferred living with her. Patient was very jealous of his two siblings, an older brother, a schizophrenic with a short history of hospitalization, and a younger sister.

Patient was enuretic until 9, a thumbsucker, who had night terrors. He was thin and a poor eater as a child. He stated that after the divorce he felt like a football being kicked between his father's home in one city, and his mother's home in another. There was only brief mention of two girl friends in patient's life by his parents, and patient did not seem unduly upset by any incident concerning them; yet one of his suicide notes was to his latest girl. He was found accidentally after he had taken the massive dose of sleeping pills.

DISCUSSION

In clinical evaluation of suicidal potential the role of depression has always been considered to be paramount. A few studies in children indicate that this is not true with children, and our study would suggest that it is not true with adolescents. One might say that since the majority of our patients were from a hospital population one would expect the schizophrenics to predominate. Though this is true, 4 of the 5 outpatients were also diagnosed as schizophrenic. Clearly, more work is needed to establish whether or not these suggestive findings can be corroborated. However, the predominance of schizophrenic psychopathology in adolescent patients attempting suicide warrants emphasis and investigation. Psychiatrists and other physicians, as well as school masters

and teachers, customarily look for depressive features as the primary type of pathology about which they might worry in terms of suicidal ideas or attempts. It would seem that it is the schizophrenic adolescent who warrants more attention. In our group of patients we noted that the clinical paranoid and catatonic types were the characteristic ones that showed such tendencies. In only one female were there any hebephrenic features and none of the patients was of the simple schizophrenic reaction type. Specific pathology included dissociation, hallucinations, delusional ideas, withdrawal, suspiciousness, and lack of communicability. In many of the patients there were also depressive trends, but these were not necessarily present or when present, obvious. Whether or not there was attempt at communication with other individuals such as parents or extra-familial loved objects could not be specifically ascertained in each situation. Certainly it was present in some instances.

The picture of the adolescent patient who will attempt suicide may be reconstructed in approximately the following way: He or she is an individual who is delusional in varying degrees, withdrawn, spending a considerable amount of time in fantasy activity, with little if any somatic complaints, but constructing a picture of supposed wrongs done to him by associates, parents, or siblings. This individual may show very little by way of overt anxiety and might or might not have complaints of feelings of depression. Sleep and appetite may be totally undisturbed. This picture contrasts quite sharply with the depressive reaction ordinarily seen in the adult who makes a suicidal attempt.

CONCLUSIONS

1. The prevalence of suicidal attempts in adolescents has been obscured by the paucity of completed suicides in that period.

2. In adults the relationship between affective disorders and suicide has been es-

tablished. In adolescents it would seem that this relationship exists between schizophrenic reaction and suicidal attempt rather than affective disorder and suicidal attempts.

THE CONCEPT OF PSYCHIC DETERMINISM

RONALD W. ANGEL, M.D.¹

Psychic determinism is generally considered to be a basic tenet of psychoanalysis. Thus, according to Ferenczi(3), "Psychoanalysis . . . stands upon the firm foundation of the strict determination of psychic happenings." What is the meaning of psychic determinism? Is it a scientific principle, or merely a useful catch-word? The purpose of this paper is to define and evaluate this important concept.

Although the concept is often treated as self-explanatory, some authors take pains to clarify its meaning. Hence one may formulate definitions based upon actual usage. In order to do so, this paper will present a number of excerpts from the literature of psychoanalysis and the philosophy of science.

PSYCHIC DETERMINISM AS A FORM OF CAUSALITY

According to one usage, psychic determinism may be defined as the proposition that all psychic events are causally determined. The notion of causality is represented as a fundamental axiom or postulate of science, with the implication that those who doubt it cannot possibly share in the scientific outlook on the world. This view of determinism is expressed in the following passage from Freud. Here he is discussing the person who does not understand the need to explain trivial errors and slips of speech :

What does the man mean by this? Does he mean to maintain that there are any occurrences so small that they fail to come within the causal sequence of things, that they might well be other than they are? Anyone thus breaking away from the determination of natural phenomena, at any single point, has thrown over the whole scientific outlook on the world (*Weltanschauung*) (5).

This passage leaves little doubt that Freud looked upon psychic determinism as a logical consequence of the causality principle, which he considered as indispensable. His viewpoint is stated even more

forcibly in the following quotation from Schilder :

Freud believed in the absolute determinism of psychic experiences and was not inclined to believe that there is any freedom in the stream of consciousness. . . . He believed in the causal connection of psychic processes. . . . The psychic experience A may be the cause of the experience B. Psychoanalysis believes that whenever there is an inner, psychic connection between two experiences, there is also a causal connection. . . . There is no difference between so-called psychic causality and physical causality(11).

Ferenczi, like Freud and Schilder, states unequivocally that he considers psychic determinism to be an application of the causality principle :

We have long been familiar with the thought that there is no chance in the physical world, no event without sufficient cause ; on the basis of psychoanalytic experience we have to suppose just as strict determination of every mental activity, however arbitrary it may appear(4).

In this passage, Ferenczi justifies determinism "on the basis of psychoanalytic experience," as an empirical finding. Freud, on the other hand, looked upon determinism as valid independently of experience and observation, a necessary part of the scientific outlook. This difference of opinion will be discussed later in the paper.

The principle of causality has a long and respectable history which may be traced as far back as ancient Greece. For centuries it was considered as a fundamental axiom of science, but recently it has fallen into disrepute(10). In the advanced physical sciences, statements about "cause and effect" are no longer found. They have been replaced by equations in which there is nothing that could be called "cause" and nothing that could be called "effect." In everyday parlance one still says that gravity causes the stone to fall, but such crude formulations have no place in advanced physical theory. It is not within the scope of this paper to evaluate the causality

¹ VA Hospital, Hines, Ill.

principle and its role in modern science. It will suffice to mention the opinion of Russell:

The law of causality, I believe, like much that passes muster among philosophers, is a relic of a bygone age, surviving, like the monarchy, only because it is erroneously supposed to do no harm (10).

Psychoanalysts are, of course, aware that physical science has changed radically since the time of Freud. Some have been concerned about the fact that causality is no longer recognized as an axiom in physics. The dilemma has been discussed by Rado:

Indeed, all our scientific reasoning has become so intimately intertwined with the idea of determinism that a science lacking this concept is altogether unthinkable. Yet there exists a large number of facts which prove with indubitable certainty that this conviction is unfounded and that scientific research can tranquilly proceed, albeit the bed-rock of causality has been forsaken (8).

If psychic determinism is the "firm foundation" of psychoanalysis, and if this "bed-rock" has been forsaken, then what is the fate of psychoanalysis? Must the analysts revise their basic assumptions in order to conform to changes in physics and the philosophy of science? Schilder would answer in the affirmative:

We do not have the right to retain a concept which corresponds to principles of physics which are no longer valid and to still model our psychological theories according to these concepts (11).

Others would feel that there is no reason why the concepts of psychology must be restricted to those of physics. Thus Rado advocates that psychoanalysis should cling to the deterministic point of view:

Psychoanalysis has but recently begun to exploit the immeasurable advantages that the deterministic viewpoint affords it and it will have to work hard to exhaust the possibilities of that principle. . . . We cannot see when and at what point in our work the statistical view, or one as yet unknown, will oust determinism from the domain of psychoanalysis. But I should not be surprised were psychoanalysis to succeed in attaining a complete understanding of our mental life with its deterministic manner of viewing things (8).

Rickman is another of the psychoanalysts who have recognized that causality is no longer an axiom but merely a dogma. Like Rado, however, he advocates that the analysts should retain it as a heuristic principle (9). In support of this opinion, one should observe that the notion of cause and effect is still widely employed in medicine. Standard textbooks continue to discuss the "etiology" of diseases, and researchers are still looking for the "causes" of various ailments.

The analysts are, of course, in the best position to know which concepts are most useful in their own research. If they are not prepared to abandon psychic determinism, then it would seem desirable to redefine that concept in terms that do not involve a rejected principle of physics. It is, in fact, possible to frame an acceptable definition without reference to causality.

DETERMINISM AND THE FUNCTION CONCEPT

In advanced sciences, causal explanations have been replaced by formulas involving the concept of a function. As a matter of theoretical interest, it would seem worthwhile to redefine psychic determinism by means of the newer concept, if only to demonstrate that psychoanalysis need not depend upon the causality principle. To a person encountering the new definition for the first time, it would no doubt seem artificial and too general to be of any great use. In this connection Russell has made the comment:

No doubt the reason why the old "law of causality" has so long continued to pervade the books of philosophers is simply that the idea of a function is unfamiliar to most of them, and they therefore seek an unduly simplified statement (10).

A function of a variable x is defined as a second variable y so related to x that whenever a value is assigned to x , a corresponding value of y is uniquely determined (12). This relationship is expressed in the familiar notation:

$$y=f(x).$$

The correspondence between values of x and y need not be made by means of what is usually called a mathematical expression, but may be determined in any way whatever, provided that whenever a value is

assigned to x a corresponding value of y is uniquely determined (7).

Using the concept of a function, Russell has defined a deterministic system as follows (10) :

A system is said to be "deterministic" when, given certain data e_1, e_2, \dots, e_n , at times t_1, t_2, \dots, t_n respectively, concerning this system, if E_t is the state of the system at any time t , there is a functional relation of the form

$$E_t = f(e_1, t_1, e_2, t_2, \dots, e_n, t_n, t).$$

Let E_t be the state of the psyche at any time t , and let e_1, e_2, \dots, e_n be data concerning the psyche at times t_1, t_2, \dots, t_n respectively. Then psychic determinism may be defined as the proposition that every psyche is a deterministic system, as that term is used by Russell.

The generality of this definition depends upon the freedom that it leaves in the choice of the functional correspondence. The task of psychology would be to discover the nature of this correspondence, the functional relation or "law" by which E_t is determined.

This definition of psychic determinism is more general than anything proposed by the analysts. It is, in fact, so general that it almost forces us to take a deterministic point of view. As Russell has pointed out, if formulas of unlimited complexity are allowed, then any system, whose state at a given moment is a function of certain measurable quantities, must be a deterministic system, must be subject to laws. A definition in such broad terms does not agree very well with the usual conception of determinism. It implies merely that the psyche conforms to laws, which may or may not be too complex for us to discover. In order to make the definition usable, one must add the provision that the laws involved are limited in complexity, capable of being apprehended and written down.

Speaking broadly, all scientific research is predicated upon confidence that the world of experience conforms to discoverable laws. A recent Nobel prize physicist has stated, "One learns to hope that nature possesses an order that one may aspire to comprehend" (13). In the physical sciences, this hope has been richly fulfilled; quite simple laws have hitherto been found to

hold. Does the field of psychology justify a similar confidence? This question cannot be answered *a priori*, and it would be fallacious to argue inductively from the state of the advanced sciences to the future state of psychology.

PSYCHIC DETERMINISM AS AN EMPIRICAL HYPOTHESIS

As mentioned above, psychic determinism has sometimes been presented as an *a priori* necessity and sometimes as a discovery based upon experience. In a passage already quoted, Freud spoke of determinism as an integral part of the scientific outlook on the world. Elsewhere in his writing, he seems to consider it as an empirical hypothesis. He had found that certain neurotic symptoms, faulty actions and dreams could be understood if viewed in the light of psychoanalytic theories. Although the theories applied in particular cases, Freud was unwilling to dogmatize about their more general application :

Does the solution given for faulty and chance actions apply in general or only in particular cases, and if only in the latter, what are the conditions under which it may also be employed in the explanation of other phenomena ?

In answer to this question my experiences leave me in the lurch. I can only urge against considering the demonstrated connections as rare (6).

Freud was quite willing to consider the possibility that other factors, possibly of a physiological nature could explain the same type of phenomena that are dealt with in psychoanalysis. This open-mindedness is shown in the following statement :

If in the demonstrations of faulty and symptomatic actions, we separate the unconscious motive from its coactive physiological and psychophysiological relations, the question remains whether there are still other factors within normal limits which, like the unconscious motive, or a substitute for it, can produce faulty and symptomatic actions on the path of these relations (6).

Recent developments in neurophysiology have suggested that there may be "still other factors" of a physical nature which provide the mechanism for random mental activity. While it is not within the scope of this paper to present these mechanisms

in detail, one of them will be discussed briefly.

A PHYSIOLOGICAL BASIS FOR RANDOM EVENTS IN THE BRAIN

Eccles(2) has stated that there are vesicles on the axon side of the synapse which apparently contain a "transmitter substance." These vesicles are so tiny that, in accordance with the Heisenberg uncertainty principle, their location is uncertain during any one millisecond. Changes in the location of these vesicles could have an appreciable influence on the excitatory efficacy of the synaptic knob. If the recipient neuron is poised at a critical level of excitability, then this "influence" could raise or lower the probability of trans-synaptic firing. A discharged impulse would in turn have an excitatory influence upon hundreds of thousands of other neurons within 20 milliseconds. Thus, at any instant, the "critically poised" neurons would serve as effective detectors and amplifiers of random events at the synapse. Here is a possible mechanism whereby random alterations may occur in the patterns of cortical excitation(1).

If one accepts the view that mental phenomena are correlated with the patterns of cerebral activity, then the existence of random factors in neuronal excitation could have profound implications for psychology. Does the flexibility and unpredictability of human thinking depend, to some extent, upon chance occurrences in the brain? Does the brain contain a "Maxwell's demon" whereby random, kaleidoscopic patterns are sorted out and used in the service of biological needs? Is there a normal equilibrium between random and non-random activity, which is disturbed in psychiatric patients? These are a few of the questions that arise when one considers the possibility that cerebral activity is partially randomized.

If psychic determinism is viewed not as an axiom but as a hypothesis based upon experience, then it must be subject to change in the light of new discoveries. As Rado has foreseen, a statistical point of view may some day replace determinism in the realm of psychology.

SUMMARY

Psychic determinism is a basic tenet of psychoanalysis. It is commonly defined as an application of the causality principle to psychic occurrences. Causality, however, is no longer accepted as a basic postulate in the advanced physical sciences. This dilemma is recognized by the psychoanalysts, who nevertheless would prefer to retain a deterministic point of view.

Psychic determinism may be defined without reference to causality, by using the mathematical concept of a function. Whether or not the psyche is a deterministic system, in the mathematical sense, cannot be decided in the present state of our knowledge.

Regardless of the definition chosen, psychic determinism is best regarded as a working hypothesis, which cannot be established on *a priori* grounds.

THE USE OF SEPARATION AS A DIAGNOSTIC MEASURE IN THE PARENT-CHILD EMOTIONAL CRISIS^{1, 2}

JOHN A. ROSE, M.D., AND MEYER SONIS, M.D.³

For almost three decades, pediatrics, child psychiatry and child welfare have been influenced deeply by the discoveries of damage in child development through traumatic separation. As a consequence of discoveries such as those of Bakwin(3), Spitz(4, 5) and Bowlby(6), there has been a considerable reaction against procedures in medical or social service which separate children from parents or their surrogates. Doctrines in child welfare have tended to abolish institutional care of infants. During the past few years, the number of children in foster care has decreased from 27,000 to 7,000 in Philadelphia, while the number held together in families by A.D.C. grants has been increased to 44,000 in Philadelphia. Further confirmation of this belief in damage to child development through traumatic separation was found in the situation of most state institutions for mentally defective and emotionally disturbed children. With inadequate staff and facilities, poor intake and admission policies, an increased number of children were "dumped" on them for care, creating a static population of children who could not be returned to the community.

Most hospitals for children have been less affected by doctrines but in most instances have relaxed former restrictions on visiting and have emphasized adequate preparation of children for anesthesia and operations. When the child is an outpatient in a general or a children's hospital, it is seldom that emotional disturbance is considered as potentially benefiting from inpatient study, and until recently there has been general reluctance to hospitalize children except as a last resort.

It may be supposed that the combination of doctrines against separation and current experience in mental and general hospitals,

have tended to militate against the development of any constructive doctrine of therapeutic hospitalization or separation as a tool for the study of highly disturbed family interaction.

In brief, then, theory and practice seem to have led to a viewpoint that equated separation of child and parent with traumatic consequences. Separation for psychological reasons was the end of the road, and hospitalization was the final stage of poor prognosis. The need to maintain the child in his home, to keep families intact, to keep a marriage together, apparently acted to obscure the facts pointing to an opposite course of action. The possible causes of the trend appear to be less important than the negative value given to separation. This view did not allow for such considerations as partial relief to the vicious cycle of parent-child destructiveness: the positive value of hospitalization; allowing child and parent to be away from each other in order to reorganize themselves constructively for future family living(7, 8); and to give opportunity for a family to test out their capacities to support each other or to find their incapacity to do this.

The intent of this paper is to examine this doctrine of separation in the light of our experience and to propose further exploration of the value of timely and structured separation of child and parent in an emotional crisis. From our experience over a 10 year period, we discovered the operation of a doctrinal paradox. On the one hand, we were supporting and teaching the value of maintaining child and parent unseparated. We proposed lessening restrictions on parent visiting in Children's Hospital of Philadelphia, and pressed for greater liaison among the parents-child-hospital-physician group. We subsidized a casework program in the hospital, in order to aid (among other things) the parent in remaining related to the child in the hospital and to assume increased responsibility for preparation of the child for medical

¹Read at the 115th annual meeting of The American Psychiatric Association, Philadelphia, Pa., Apr.27-May 1, 1959.

²Based on the concept of "Crisis," as described by Lindemann, Caplan *et al.*(1, 2).

³1700 Bainbridge St., Philadelphia, Pa.

and surgical procedures. We indoctrinated pediatric residents to the end of preventing damage to child development through traumatic separation. At the same time in our community child guidance clinic, we attempted to treat severely disturbed children and their parents in the home. In our attempts to treat the severely disturbed child in foster placement, we avoided hospitalization. We failed to consider, in consultations with child care agencies, the possibility that the disturbance was greater than the agency should attempt to manage. We shared with the school a belief that the school should provide for all levels of disturbance. In brief, this was a trend in the direction of avoiding separation of child and parent.

On the other hand, we found ourselves involved in a series of experiences which indicated a shift in the direction of practice. In individual cases there seemed to be value in temporary separation between the child and parent involved in an emotional crisis. It is our belief that brief review of these experiences may be of value in the further exploration of the notion that separation of child and parent need not be a traumatic or destructive experience in child development.

The pediatric care situation in Children's Hospital of Philadelphia has been an interesting laboratory in which to evaluate the paradox of doctrine and practice which has been suggested. Over the years, parents were involved to a greater extent in the total management of the hospitalized child. As parents ceased to be seen as foreign bodies, whose only intent was to delay nurses' procedures, cause infection, badger physicians, and destroy the value of the housekeeping staff, the management of the child in the hospital became easier. The child with rheumatic fever became more tractable in following the regimen of rest, once he became assured through experience and help that his parents had not abandoned him; the child on a deprivation diet, for medical studies, was able to tolerate his anxiety to a great extent with parental help and involvement; the child receiving anesthesia responded to smaller doses of the anesthetic and arrived more readily at a relaxed stage when adequate

support from parents was facilitated. In brief, a child was better able to manage his fears of abandonment, mutilation or injury through greater parent involvement and participation in the process of hospital care. However, there were exceptional situations in which continued visits of parents did not bring about a more tractable or better adjusted child. In the past the parents were told, in essence, that they were bad for the child and should not visit. In these situations, temporary relief was obtained, in that the child became more tractable, but in some situations the hospital ended up with apathetic, listless and withdrawn children, an abandoned child, or a child who showed greater long range disturbances. We discovered that structured, non-punitive, and participating separation of child and parent and separate assistance to each would permit the emergence of constructive experience for both parent and child.

The case of Gary B. parallels other situations of similar nature though in children with other illnesses, and seems sufficiently typical to illustrate the generic situation and its constructive possibilities.

Case 1: Gary, a 27-month-old white boy was hospitalized for about 4 weeks, following the initial presumptive diagnosis of early ulcerative colitis. The pediatrician prolonged hospitalization to explore both the physical and emotional aspects of the presenting problem in Gary and his family.

Arrangements had been made for Mrs. B. to sleep in the hospital with Gary. As a result, Mrs. B. seldom left Gary and Gary almost never left his mother. Mrs. B. was cooperative in allowing all necessary medical and nursing procedures to go on, but dominated the perception of the child and his condition by her many fears and pressures. The child seemed to perceive all values in the same way as his mother. The continued presence of Mrs. B. made independent evaluation of Gary's status with respect to play, sleep, peer relationships, adult relationship, eating, toileting impossible. The frustration to all personnel, from pediatric residents to housekeepers, was so great that they were ready to punish Mrs. B. The theoretical and practical issue was whether this tight union of Gary and his mother was an authentic defense against the anxiety of the illness and hospitalization, or

whether it was representative of an enduring pattern which was one of chronic infantilization, essentially depriving the child of ego nurturing. Were we dealing with constructive support to the child or a pathological regressed symbiosis?

It was decided to confront the parents with the diagnostic necessity of, and a plan for, temporary structured separation. Anticipating the parental reaction to separation, we discussed with them their views with respect to emotional factors as a part of Gary's illness. Both parents had been quite defensive about any such consideration previously, with the mother's attitude stronger than the father's. The father and mother, age 37 and 32 respectively, prior to this event had given histories of "normal and usual" childhood and adult experiences: completely "normal and usual" experiences in their 11 years of marriage; completely "normal" development of Gary. Normal despite a history of: sterility that existed in the first 5 to 6 years of marriage, followed by conception of a girl (age 6); and infertility for 2 years following this, ending in conception of Gary. They had resided with Mrs. B.'s mother for all 11 years of marriage and in the same house in which Mrs. B. was reared as a child. At age 27 months Gary was on a diet of baby food, held in his mother's lap for bottle feeding, did not talk very freely, and was extremely shy of strangers and children.

As Mrs. B. explored the possibility of separation, she reiterated her fears that Gary might climb out of the crib and get hurt, get into things that he shouldn't, go to the bathroom and tamper with things; he might feel lonely and angry and resent the attentions of the professional staff. With support and realistic reassurance, Mrs. B. was able to prepare Gary for this separation.

A separation was achieved in this structured way and it was possible to evaluate Gary more realistically. His reaction to separation was minimal. He cried when his mother left him at the elevator and was mildly depressed for a few minutes. He expressed anger when his physician started to leave him, he clung and kicked at a nurse but quieted down and played subsequently. He was now ready for diversification of foods and more systematic self feeding. Psychological tests could be done, and he achieved an I.Q. of 118. Medical procedures could be accomplished in a shorter

time and with less upheaval than before. Through introduction to play groups of peers and through adult relationships it was possible to evaluate his capacity for object relationship beyond his mother. The separation demonstrated a developmental spurt rather than regression.

For the mother, the separation resulted in self-confrontation with the relevance of her fears. She began to perceive her own infantile self image and her sense of inability to perform as her husband wished. She was prepared for seeing the developmental spurt in the child when she began to visit again. Thus she was able to grasp that her own defenses against mature expectation of herself, projected upon the child, resulted in infantilization of the child.

This type of crisis situation(2) is becoming more common. We are now seeing an increasing number of severe psychosomatic conditions in very young children. The pediatrician confronted with a worsening ulcerative colitis in a young child may find that the doctrine against separation plays into fixed defenses of parents. Under such conditions, it frequently happens that the parental neurosis is made worse by resentment on the part of physicians and hospital personnel toward the mother's implication in the crippled developmental capacity of the child. In general, we speculate that the threat of hostility directed at the mother increases her need to perceive the child as helpless and oppressed while increasing her defenses against psychogeneity of disease in the child since this is equivalent to an accusation of inadequacy. The maternal hostility increases toward aggressive manifestations in the child, thus increasing the intensity of the psychosomatic symptom. The structured separation breaks into the total circular interaction allowing non-defensive assessment of the situation and the breakdown of systematic projection of maternal defenses upon the child. It should be emphasized that punitive separation would be likely to be traumatic on both sides. Thus, in hospital practice, as a usual condition, close relationship in visiting is mutually supportive to the child's capacity to bear stress and to the parental ego adequacy. Exceptions

to the rule indicate that separation of special type may be necessary in order for the experience to become supportive. It is characteristic today to find that the developmental crises of young children and parent-child interaction involve the pediatrician and pediatric facilities in such a way that failure to comprehend the proportions of the crisis and to use separation as a form of preventive intervention will probably result in a worsening situation. It is this situation which fulfills the elements of a developmental crisis in that at the time of a critical period or event, there exists the possibility of definitely improving or worsening the developmental situation.

In a similar manner, the spontaneous behavior of certain families and children in a crisis of acting out afforded us opportunity in the outpatient setting of the Philadelphia Child Guidance Clinic to further understand the dynamic possibilities of structured and timely separation.

The case of Larry J. illustrates a situation in which there were recurring crises and in which no intervention was possible until separation was forced by the action of the child. In this case, 4 different attempts to secure help from a psychiatric outpatient clinic for children failed apparently because the possibility of separation was not considered.

Case 2: When Larry was 5½, the case was referred following a major fire set by the child in the living room of his house. In an initial interview the mother described the child as having been irritable and bad tempered since birth and gave a history of breaking him of temper tantrums by whipping. She also broke him of head-banging punitively. The mother described herself as frequently ill, needing rest and needing to ask others to look after the children. (There was a girl of 1 yr. at this time.) She described this patient as always after her to do things for the younger child and not letting her sleep or rest. The mother failed to show up for subsequent appointments and found numerous excuses for not continuing in response to follow-up phone calls.

Over the next 5 years the mother made 3 more appointments on an emergency basis but did not continue with her intention until the last, at which time the child was 11½. By then, his case had involved the school through

learning and truancy problems; a protective agency had had several contacts because of cruelty complaints and several other psychiatric facilities had been through a similar experience as that of our clinic. Larry was now described as seclusive and untouchable, enuretic, taken to alternately looking after his siblings and then withdrawing, often a truant.

In the course of therapy he was withdrawn as long as his mother was adequate and supportive. At the point where she would become ill, he would minister at first to all her needs and take care of the other children. Following several days of this, he would suddenly show disruptive behavior in school and run away from home. Essentially, there was no accessibility to treatment until the mother showed herself unable to carry parental responsibility. At this point the child would flee the home. The case terminated when he precipitated institutionalization by running away for a protracted period and showing massive disturbance when apprehended.

The record in this case was distinguished in that at no time was the mother offered the possibility of separation from the child.

In this case as in many similar ones, the presenting symptoms brought to the psychiatric clinic for children do not represent an average neurotic interaction in which the application for service is an emotionally responsible and relatively mature move on the part of the parents. It is rather that the acting out behavior of the child is hostile and destructive and so induces awareness in the parents of their own hostile, destructive impulses. Application for service represents flight from the situation and defense against the strong negative impulses.

The original common elements of the cases are almost standard. Both father and mother have histories of emotional deprivation. Marriage seems adequately fulfilling until the birth of a child. The pregnancy and early child care experience increase the mother's anticipations of excessive output and little reward. She is inconsistent in her mothering and increases the demand for care from her husband. He takes emotional flight from her demands and rage reactions. She now perceives the child as the object from which stems her sense of being treated unfairly and reacts with increasing rage to the demands of the child, with intermit-

tent periods of guilty over-compensation in giving to him. The mother and child then alternate between closeness and infantile giving to one another and sudden rage reactions to frustrated expectancy. Physical violence on the part of the mother in early punishment predicts overt destructiveness in the acting out of the child.

Such cases tend to seek clinic help after a particularly frightening act of the child. The repressed wish in the mother is to receive rather than give, to flee the care of the child and avoid guilt, and to flee her own impulses of retaliation toward the child. The tendency on the part of professional personnel to promote family unity is experienced by the mother as a further aggravation and demand. Primarily she seems to need immediate relief of guilt in order not to continue her flight. It appears to us that the doctrine against separation has acted to prevent the possibility of intervention in the case.

One of the more important therapeutic trends has been that of better understanding of counter transference phenomena and the impact of such factors on the outcome of almost any operation with patients. In this sense, it seems likely that the doctrines against separation have added to the counter transference factor operating against separating child and parent. The case of Jackie W. illustrates these points.

Case 3: This 12-year-old boy had been the object of numerous psychiatric studies and attempts at treatment in the preceding 4 years. The history resembled that of Larry J. There had been recurrent crises of fire setting, runaway behavior, school problems, overt theft, which came to a head in family violence. Mother and father were disturbed and had histories of emotional deprivation. The mother dominated the family.

Psychiatric inpatient care had been recommended several years before but had not been accomplished. Unfortunately the dearth of adequate facilities seemed not to allow the placement, though there were undoubtedly reinforcing factors.

We decided to attempt outpatient treatment with an arranged understanding that inpatient treatment and separation should be considered immediately if difficulties arose. In treatment the boy became resistant while at the same time the mother became more openly author-

itative in her expectations toward the patient and toward her husband. The therapist expressed the idea to the caseworker seeing the parents that a crisis might be in the making again. This idea was not well received but the patient took matters into his own hands. He precipitated a severe crisis at school and the school administration moved quickly to place the boy in a residential school. When the therapist supported the school in this move, the caseworker was dismayed and surprised. She claimed no basis for expecting this, despite previous dictation in the clinic record indicating that separation should be considered in the event of another crisis.

In the separated situation, 3 clear diagnostic factors emerged which had been previously concealed. The boy, with whom treatment was continued, became highly verbal and revealed a secret sense of special responsibility for his mother's welfare. Away from her he forgot his rage at her rejection of his masculinity and remembered that she was easily lost, and worried about her.

Essentially there was revealed in both mother and child a tender and highly sexualized fantasy construction of the other which opened the door to understanding of the tremendous anger acted out when the fantasy proved inconsistent with reality. During the first week of separation the mother wrote 12 letters to the boy reminding him they could be together by praying at the same time every night.

The other concealed factors in this family interaction came to light when the father, receiving from his adolescent daughter the understanding of his needs rejected by his wife, acted out incestuously with the child.

This case served to considerably strengthen our conviction that separation should be more often selectively considered as a matter of choice rather than waiting for the case to force the issue as a matter of ultimate bad prognosis. It was clear that prognosis was bettered through separation and equally clear that counter transference attitudes reinforced by the doctrine against separation was a real factor in the management of cases of this type.

Our findings were interesting enough to apply in a different type of situation,

which still had the child as an object upon whom disturbance could be projected and displaced. In this situation, we were attempting to study gastrointestinal symptoms in infants under 6 months of age, as reflections of disturbed mother-infant interaction. The problem posed was one of attempting to determine the primary cause: were symptoms primary or secondary to mother's disturbance? was the infant's activity autogenic or reactive? A project was evolved and continued for 5 years, in which an open-ended hospitalization of the infant was attempted, with possibilities of both physical and emotional factors as etiologic; continued observation and study in a neutral environment; structured 48-hour separation of infant and mother in the first 2 days of hospitalization; interviewing the mother on each of the days of separation, and tape recording each interview. Not only was this structured separation useful in determination of the clinical resting state of the infant, but it also acted as a vivid stimulus in tapping the entire area of maternal disturbance.

The following two cases are illustrative of some of the findings of this project:

Case 4: Doris A., a 3-months-old Negro female was the third child of a 24-year-old mother and a 61-year-old father. Pregnancy was complicated by vomiting; labor and delivery were uneventful, with no neonatal difficulties. Doris was breast-fed and began vomiting at 1 week of age continuing until the present. Supplemental feedings were added, formulas were changed, sedatives and antispasmodics given, but to no avail. Vomiting continued on milk, water or solids. In addition to the vomiting, a history was obtained of irritability, crying and inability of the mother to soothe the child. Hospitalization with structured separation was arranged, and as with many of the babies in the project, vomiting ceased within a day or two while maintained on the same formula as prior to hospitalization, irritability diminished, and all studies including C.B.C., urinalysis, g.i. series, stool examination, were within normal limits. During the interviewing of Mrs. A., a picture emerged of a woman who was literally pouring herself into the infant; unconsciously Doris had become the means of proving to the world, Mrs. A.'s family and herself, that she (Mrs. A.) could be a more adequate mother

than her own mother; with much of this related to her own deprived childhood, need for dependence, and therefore an early marriage to an older man who required more than he could give, and a history of psychotic breakdown in the 2 previous pregnancies.

Case 5: Charles K. was a 4-month-old white boy, the only child of a 19-year-old woman. His father had been killed in an automobile accident when Mrs. K. was 8 months pregnant. Pregnancy was complicated by repeated attacks of cholecystitis and depression. Labor and birth were uneventful, with no neonatal difficulties. Ever since Charles was one week of age, vomiting has been a problem. Frequent formula changes and a previous hospitalization in another institution did not alter the picture. Hospitalization with structured separation was arranged. All studies were negative, the baby did well, and vomiting was quite slight. During the initial separation interview, Mrs. K. reported a dream of the previous night in which she felt that she had to give Charles away or he would starve to death. A picture emerged, in the interviewing, which very much confirmed her dream. Unconsciously she was literally feeding on the infant herself; by projection and displacement he had become her replaced husband; he carried many of his father's features and personality; he became her sole means of comfort as Mrs. K. would hold long discourse with him about her loneliness and pain.

CONCLUSIONS

As a result of these experiences, we are convinced that a valuable diagnostic tool has been overlooked in child psychiatry. We decided to set up an acute inpatient service for pre-adolescent, emotionally disturbed children, based on the notion that a short period of carefully structured separation at the time of a crisis may be a valuable diagnostic tool in permitting a more intensive and extensive evaluation of intrinsic problems in child and family. It should be emphasized that this notion does not negate the general principles of support for children to live in warm family relationships rather than apart from them. However, this notion does allow for exceptions to the rule; all children are not best off in their own families; structured and realistic separations are not inevitably traumatic and the door is open to the temporary separation of children with hospital placement as a relieving and elective diag-

nostic tool rather than inevitably as a last resort.

THE DISTRICT BRANCH OF THE APA: ITS ORIGIN, PRESENT STATUS, AND FUTURE DEVELOPMENT¹

WALTER H. OBENAU, M.D.²

Founded in 1844 as the Association of Medical Superintendents of American Institutions for the Insane, continued from 1892 to 1921 as the American Medico-Psychological Association, the American Psychiatric Association is the oldest medical organization of national scope in North America. It has a history of which its members can justly be proud, for it has continuously served to advance the most enlightened treatment for those suffering from mental and nervous disorders, and has maintained from its beginning an authoritative position in the continuing effort to improve the treatment of the mentally ill.

In the beginning, it appears that the Association had little, if anything, in the way of a written constitution or by-laws, although the objectives seem to have been well understood. The 1892 Constitution stated, "The object of this Association shall be the study of all subjects pertaining to mental disease, including the care, treatment and promotion of the best interests of the insane." This same wording, with the words, "epileptic, feeble-minded and allied classes" added, was carried over in the revised constitution adopted in 1921. The present wording of Association objectives was adopted in 1933, and reads as follows,

(a) to further the study of subjects pertaining to the nature, treatment, and prevention of mental disorders; (b) to further the interests, the maintenance, and the advancement of standards of hospitals for mental disorders, of outpatient clinics, and of all other agencies concerned with the medical, social, and legal aspects of these disorders; (c) to further psychiatric education and research; (d) and to apply psychiatric knowledge to other branches of medicine, to other sciences, and to the public welfare.

In order to carry out its objectives, the Association has always depended largely upon its members working in committees and as individuals on specific assignments. At first, the members were very few in number and organizational problems were comparatively simple. Starting with the original 13 Medical Superintendents, growth during the ensuing 4 or 5 decades was slow. By 1892, however, its size had increased to about 250 members. At this time, the membership designation "Medical Superintendents" was changed on the Association Roster to "Members" and Assistant Physicians in mental hospitals were for the first time eligible to be called "Associate Members"(1). A second important change in this respect occurred in 1921, when physicians other than those practicing in institutions for the insane became eligible for membership(2). At the same time, the category of "Fellow" was established, and those previously called "Associate Members" became "Members." To be sure, these changes reflected the tempo of the times, especially the fact that, following World War I, increasing numbers of psychiatrists began to practice their specialty outside the confines of a mental hospital. This embracement by the Association, of all psychiatrists, no matter what their individual interest—be it adult or child psychiatry, psychoanalysis, forensic psychiatry, or any other acceptable form—had profound effects. In 1921, when the Association adopted its present name, there were about 1,000 members. In 1934, the year after the category of "Associate Member" was re-established, there were 1,604; and by 1944 this had increased to 3,387. Following World War II, the growth curve of the Association rose steeply (see graph) and as of May 1958 there was a total of 10,536 members of all classes. Indeed, it is this very growth and the resulting complexity of demand and responsibility thrust upon the Association that has made the District Branch and the Assembly of District Branches not only a

¹ Read at the Milwaukee Neuropsychiatric Society, March 18, 1959. Revised May 15, 1959.

² Immediate Past Speaker, Assembly of District Branches of the APA; Medical Superintendent, Pontiac State Hosp., Mich.; Formerly Assistant Medical Superintendent, Ypsilanti State Hosp., Mich.

logical step but also a necessary development.

From 1844 to 1891, all committees reported directly to the Medical Superintendent, gathered at the annual meeting. Since 1892, the Association has been governed by an elected Council, which receives all committee reports and makes recommendations to the membership at the annual meeting. That this system has prevailed for so long a time is a tribute to the wisdom and devotion of the many distinguished Fellows of the Association who have labored through the years to carry on the work of the Council; theirs has been a labor of love often carried on at considerable personal sacrifice with their chief reward being simply the satisfaction of their accomplishments; and perhaps, the applause of their fellow members. Nevertheless, it became increasingly difficult for this small group of individuals to reflect the feelings and wishes of the membership, and rumblings of discontent began to be heard with increasing force.

The Assembly of District Branches as now constituted has been the outgrowth of various arrangements that have been tried. In 1927, as a result of the Presidential address given two years earlier by William

A. White, the by-Laws were amended to provide for "Sections" as well as for "District Societies" of the APA. The "Sections" were to be any National Society with similar interests who wished to become an organic part of the Association. Provision was made to assimilate their treasuries as well as their memberships but non-APA members were to be kept on a separate list and they would have no voice in the affairs of the Association. This arrangement soon outlived its potential usefulness, however, and it was abandoned in 1936. The "District Societies," on the other hand, beginning with the Massachusetts Psychiatric Society in 1931, flourished - perhaps due to the degree of local autonomy they enjoyed under Section 2, Article V of the by-Laws, which stated: "Local organizations shall be allowed to include members who are not eligible for membership in the Association and shall in general be allowed a wide latitude in their organization." The benefits looked for from the District Society were summarized by President Kline as: 1. To provide information regarding candidates for membership in the Association. 2. To stimulate the holding of more frequent sectional meetings so that members could

AMERICAN PSYCHIATRIC ASSOCIATION GRAPH SHOWING GROWTH OF MEMBERSHIP ALL CLASSES

be more active; 3. And to stimulate interest in psychiatry(3). It seems fair to say that these benefits were felt, and that they continue to be felt through the "Affiliated Societies" under which designation these organizations have continued to function since 1936. At that time as already noted, the "Sections" previously authorized were abolished, the designation of the "District Societies" changed to "Affiliated Societies," and a new category created to be called "District Branches." President Cheney had this to say at the annual meeting held in St. Louis when the changed designations were submitted to the membership for approval:

Briefly, if I may interpolate, these amendments change the designation of what has previously been called a district society to that of an affiliated society, such societies being made up of other than members of this Association. Under the present Constitution, these are district societies that are composed (not only) of persons who are members of this Association but also (those) who are not members. It has been difficult to handle that situation and the Council has given careful consideration to the matter of having such societies called district societies. The provision is made by this amendment to have, therefore, affiliated societies.

It would seem that any organization that was a district branch of an association such as this should be really a part of the parent body and be composed only of members of this Association. The term affiliation does not indicate that an association or society is a part of the parent body. On the other hand, the amendments provide that where groups of Fellows or Members of this Association wish to organize into local or district societies, provision can be made and they will be called district societies, but they shall be limited always to members and fellows of the Association(5).

Thus, the formation of "District Branches" as we now know them has been possible since 1936, but no reaction in the way of effective organization occurred for some 12 or 13 years.

The 1930's and 1940's saw great changes in the practice of medicine, including the specialty of psychiatry. Gradually, the structure of the Association began to be questioned with respect to whether it could meet the challenge of the times and pro-

vide the leadership expected by its members. There was a suspicion on the part of some that the Association was being controlled by a small autocratic group, to whom the wishes of the membership were not known; or if known, were largely being ignored. An Association report concerning this period states:

In December 1944, at a meeting of the Council of the American Psychiatric Association in New York, vigorous protest was made by various members of the Association regarding the failure of the Association to assume leadership in the field of psychiatry, to support the psychiatric work in the Army and Navy, to assist members in the improvement of their state hospitals, to further psychiatric education, and many other things(6).

A committee, under the Chairmanship of Doctor Karl A. Menninger, was appointed by President Karl M. Bowman and a most exhaustive study of the problems involved was carried on over a period of several years. The result was a comprehensive plan submitted in 1948, which would have abolished Council and set up a House of Delegates, with the executive function to be vested in a Board of Trustees.

This proposal stirred up enormous controversy and for a time a separatist movement seemed to threaten the unity of the Association. As stated by Doctor Harry C. Solomon in his Presidential Address of May 1958:

Those who were most concerned with and active in the Association's affairs tended to split into two factions. One group, many of whom were associated with the Group for the Advancement of Psychiatry, formed shortly after the War, were strongly in favor of the reorganization plan feeling that it would bring new life and leadership to psychiatry. Another group, many of whom were associated with the Committee for the Preservation of Medical Standards in Psychiatry, was more or less unalterably opposed, fearing that it would destroy cherished values, policies and procedures(7).

Under the circumstances at that time, no action on the plan was possible and only minimal changes in the Constitution and by-Laws were made in 1950. By 1952, however, tempers had cooled and it was then

possible again to amend Article V of the by-Laws and thereby to create the Assembly of District Branches and for the first time to give some real purpose to District Branch formation.

Until the Assembly came into being, the Affiliated Society held sway on the local scene, and for many years to the complete exclusion of the District Branch. This is not at all surprising, since the Affiliated Society had almost complete autonomy over its own organizational affairs, the District Branch on the other hand would be required to limit its membership to those physicians who belonged to the American Psychiatric Association. It was not until 1949, and then no doubt stimulated by the report of the Committee on Reorganization, and in anticipation of organizational change, that the first two District Branches were formed and recognized—the Pennsylvania District Branch (including the State of Delaware) and the Mid Continent District Branch (including the States of Kansas and Missouri). The authorization of the Assembly, however, provided the key that had been missing. Immediately, interest in the formation of District Branches took a sudden surge forward. Thus, at the time of the first meeting of the Assembly in Los Angeles in May of 1953, there were some 16 District Branches in being and all sent a representative to participate in this historic event.

There has been rapid growth since that time and some 49 District Branches are now in existence within whose territorial limits over 95% of all APA members live and work. Each District Branch elects a Representative to the Assembly, whose voting strength is in proportion to the number of members he represents (one vote for each 20 members; fractions of 20 not counted). The elected Officers of the Assembly consist of a Speaker, Speaker-Elect (now called Deputy Speaker), a Past Speaker, a Recorder (or secretary); and 5 members of a Policy Committee, selected from Five Areas by caucus at the annual meeting on a staggered basis to serve terms of 2 years. The place of the Assembly in the Association now seems secure, and its importance in the determination of policy becomes stronger each year. Indeed, Council has come to depend on the Assembly

for advice in ever increasing degree before taking action on any matters of major policy.

During the coming year, further amendments to our Constitution and by-Laws will be submitted for approval of the membership. These would consolidate the gains made thus far and authorize "approved" District Branches to act in the name of the Association with respect to new membership applications from within their territorial limits (provision is made for "membership-at-large" in certain situations). Because of this growth and development of the District Branch Movement, there seems to be no doubt that in time the original plan of the Reorganization Committee headed by Doctor Karl Menninger will, to all intents and purposes, be fulfilled.

Let us now turn to some of the problems inherent in the present state of District Branch development, and discuss one or two areas in which improvement might be made in order to carry out better the objectives of the Association, of the Assembly, and of the individual District Branch. The Assembly of District Branches has defined its purpose as

to represent and serve the needs of the District Branches in their relationship to the governing bodies of the APA and to represent the governing bodies of the APA in their relationship to the District Branches.

The purpose of the District Branch is stated as follows:

to represent the local psychiatric profession in the American Psychiatric Association through its delegates to the Assembly of District Branches. The District Branch will foster the progress of psychiatry, represent psychiatry in the designated local area and assist the American Psychiatric Association in promoting its aims and objectives(8).

It is my belief that the Assembly is now fulfilling its objectives in a very satisfactory manner. We do have under continuing study certain features, however, such as the possibility of improving our method of distributing voting power among the District Branch Representatives (for instance, should District Branches that have

more than 200 members be allowed more than one representative?).

With respect to the District Branches, there is likewise cause for much satisfaction. The local member is taking an ever increasing interest in the affairs of the Association. There is much improved liaison between committees working on the local scene and committees performing a similar function for the Association; and most importantly, the local member can at last, through his representative to the Assembly, have his voice heard and his opinion felt in our highest Councils. Nevertheless, there is still much room for improvement.

The representation of psychiatry in a really satisfactory and simultaneous way at both the state and local levels is one of the important areas now in need of study and action. Considerable thought has been given to this matter, and two possible solutions have been offered.

One of these is already in operation in the State of New York. There, the 10 District Branches now in that state have formed a "Committee of Delegates" composed of the Representatives and Alternate Representatives to the Assembly from the various District Branches. They get together at least 4 times a year and act for the profession at the state level. Apparently they are at present quite satisfied with the arrangement, although it has been in operation only a year or so. However, New York is unique in that it has over 1/5th of all APA members presently living and practicing within its political boundaries and for this reason has been given the status of "Area" in the organization of the Assembly. Most other states have but one, Indiana and Missouri have 2, and California has 3 District Branches. On the other hand, the Northern New England District Branch encompasses 4 states, the Intermountain District Branch has 7, and the North Pacific District Branch includes 3 states and one Canadian province.

The other suggestion regarding an arrangement whereby both local and state-wide responsibilities may be met, is one for which I have been responsible. It concerns the possibility of maintaining the size of the District Branch to coincide with state boundaries whenever there are enough APA members (such as in the State

of Wisconsin) to make this feasible. This might bear some similarity to the way the American Medical Association is subdivided into State Medical Societies. The District Branch in turn could be subdivided into local units which might be called "Chapters," much as the State Medical Society is subdivided into County Units. Members of the "Chapter" would also be members of the District Branch, and of course, of the Association. Each "Chapter" would elect its own officers, arrange its own programs, provide for its own expenses and send representatives to a "Council" or "House of Representatives" of the District Branch. Its members would be eligible for election to office in the District Branch. The local "Chapters" would possibly have meetings at monthly intervals, whereas the District Branch might have one or two meetings per year to put on scientific programs, to act on matters considered by the District Branch Council between meetings, to elect officers, and to consider instructions to be given the Representative to the Assembly.³ In this way, both local as well as state-wide and Association needs could be met. It seems to me that such an arrangement also has the advantage of giving the local member more to stimulate his interest—if he is so motivated, he can aspire to office on the local, the state, or the Association level. The increased opportunity for experience in organizational work could have great value, not only to the individual member that wants to enlarge his horizons but to the Association as well, where new talent is always needed and welcome.

We should act reasonably soon, in my judgment, to resolve this problem of state-wide and local representation and organization.⁴ Of the 49 District Branches, some 29

³ As noted earlier in this paper, study is now being given to the possibility of allowing more than one representative from a given District Branch under certain conditions. If the "Chapter" arrangement is adopted and if multiple representation in the Assembly eventually is permitted, the writer would favor having each Representative to the Assembly selected in part on the basis of geography. In this way he could be responsible personally to the membership in his territory as well as to the District Branch as a whole.

⁴ At the 1959 Annual Meeting in Philadelphia,

are now organized along the political boundaries of a single state, province or territory. In several of these—and in time no doubt in most—there will be a desire on the part of local groups to set up their own societies and thus “splinter” the existing District Branches into ever smaller units. Wisconsin is one example of where I have heard about discussion of such a movement. The inevitable result of such “splintering,” if allowed to proceed too far, would be an Assembly too large for effective action; and at the state level there would be increased difficulties with respect to coordination of effort, if not outright hostility and disunity between the splintered District Branches. When and if this situation came to pass, the entire structure of the Assembly and its component units probably would have to be rebuilt, possibly along the lines now suggested. Prudence would seem to dictate that we take appropriate action while there is yet time.

Now let us turn to another problem—our relationship as organized psychiatrists to our honored and respected colleagues such as the neurologists, neurosurgeons, internists, pediatricians—those who have been eligible for membership in our Affiliated Societies, but who do not fulfill the requirements for membership in the Association. It has long been one of the strengths of the Affiliated Society that because of its multi-disciplinary nature, a working relationship has been established that is extremely valuable. Through this relationship, the non-psychiatric members add materially to their understanding of psychiatry, the psychiatrist is kept abreast of developments in related fields, and opportunity for collaboration on the professional level is much enhanced. There also results from this understanding and fellowship an

atmosphere in which the support of our medical colleagues comes naturally when we are faced with public issues; an example of this is the legislative efforts of the clinical psychologists at the present time.

From the first it has been hoped that the closest kind of working relationship could be developed between the District Branch and the Affiliated Society. It is felt that both organizations have an important role to play on the local scene, overlapping in many areas perhaps, but each unique in its own way. The District Branch being an organic part of the APA, provides the local member an opportunity to participate in the business of the Association. Through debate and discussion, opinions are formed which can be transmitted through the Representative to the Assembly. The Affiliated Society on the other hand provides a needed relationship at the local level for liaison and organic union with our non-APA medical brethren.

Many District Branches arose in the first place from the membership of the Affiliated Societies. Indeed, the District Branch was often superimposed on the older organization. At the present time, there are 14 cases in which both organizations have been continued having the same officers, holding joint or alternating meetings, and with the closest possible relationship. Local circumstances vary from place to place, however, and here and there the older Affiliated Society has been replaced by the District Branch. In some such cases, the non-APA members have been retained as Affiliates who are welcome to come to meetings, but who have no vote and who cannot hold office. During a period of transition, perhaps a satisfactory solution might consist of maintaining both organizations as separate and distinct units that could have meetings on alternating dates (the scientific and social portions of which are open to members of both), plan their programs together, and share in common costs, such as for Speakers, rentals, etc. In this way, there would be no awkwardness of a non-APA member happened to be nominated for office in the Affiliated Society, and the dues needed might not be much greater than would be required for one Society that did all these things on its own. Another solution might consist of

APA Council adopted a resolution endorsing the encouragement of District Branch organization along State, Provincial or Territorial lines, and the discouragement of “splintering” of District Branches now covering an entire State, Province, or Territory. The Assembly was requested to consider further the concept of “Chapters” within District Branches and to present at a later date specific proposals or recommendations along this line. The subject was again discussed in the Assembly, the idea endorsed in principle, and referred for further study by the separate District Branches and by the Policy Committee of the Assembly.

liberalizing the regulations for membership in the Association itself, so that, for instance, Board Certification in a related medical specialty would qualify a physician for Associate Membership.

In any event, it must be recognized that psychiatrists, like all medical doctors, are busy people and the idea of having two local professional societies with approximately the same membership (75% of the Affiliated Society Members must be psychiatrists) and much the same interests, holding simultaneous but separate meetings just doesn't make sense.

It is my hope that practical adjustments, perhaps along the lines suggested above, can be made so that the benefits peculiar to both types of organizations may continue to be felt. I believe deeply in the democratic process that is made possible by the District Branches, but I also am concerned lest we psychiatrists permit the clouding of our identification in the public mind, and indeed, in the minds of our medical brethren, as Doctors of Medicine. The distinction between a psychiatrist and a psychologist is already a little foggy—and I think that, like a certain political party at this time, we should be giving some thought to the clarification of our public image. In that context, the abandonment of the medical liaison we have developed in the Affiliated Society scarcely seems the thing to do.

I would like to go back at this point and repeat one of the objectives as given in the Constitution of our Association—"and to apply psychiatric knowledge to other branches of medicine, to other sciences, and to the public welfare." If the District Branch is to assist in promoting this feature, it would seem only reasonable that suitable adjustments in its organizational structure should be made. Indeed, it would seem that our membership will have to decide in proper time just which of our stated Association objectives we really want to emphasize. If psychiatry, through the Association, is to provide leadership in the fight against mental illness, it would seem that we will be called upon to do somewhat more than might be expected of an organization con-

cerned only with scientific matters. The relationship between the District Branch of the American Psychiatric Association and the "other branches of medicine, the other sciences, and the public" is involved here, and much study and discussion will be required to provide proper perspective and solution.

SUMMARY

This paper has represented an attempt to summarize the facts pertinent to the development and present status of the District Branch movement that is now progressing within the American Psychiatric Association. Some reflections concerning and suggestions about organization for the effective meeting of local and statewide needs for psychiatry have been offered. The related matter of adjustments between the District Branch and the Affiliated Society has also been discussed and the need for continued liaison with our medical brethren emphasized. It is this writer's earnest hope that he may have stimulated thinking on these matters in some small degree; that constructive and fruitful discussion may follow; that out of collective wisdom flowing from the democratic process, the American Psychiatric Association may continue to maintain an organizational structure that will permit the perpetuation of her status, not only as the oldest Medical Association of National size in North America, but also as the recognized leader in the fight against mental illness as well.

A CROSS-CULTURAL APPROACH TO MENTAL HEALTH PROBLEMS¹

E. D. WITTKOWER, M.D., AND J. FRIED, Ph.D.²

Much thought has been given to the definition of the term and to the delineation of the field of *social psychiatry*. According to M. Opler(1), "the impact of social and cultural environment upon the development of personalities is the central concern of social psychiatry." This general description indicates that social psychiatry, in contrast to clinical psychiatry, invariably involves the complicated play of interpersonal relations between sets of individuals, and that it views the behaviour of such individuals against the background of, in interaction with, and in response to their socio-cultural environment. Such approach implies and presupposes a thorough knowledge on the part of the social psychiatrist of the social system in which patients under his observation live, or, more realistically, a close collaboration between psychiatrists and social scientists.

However, because the field as outlined by M. Opler(1)—ranging as it does from marriage counselling to the effect of culture change on mental health—is so wide that no single person can encompass it, it appears advisable to detach *cultural psychiatry* from social psychiatry and to treat it as a separate entity. As such the term cultural psychiatry denotes a field of research which explores the frequency, etiology and nosology of mental illness and the care and after-care of the mentally ill within the confines of a cultural unit and in relation to the cultural environment concerned. The term "culture" has gradually emerged from the studies of anthropologists to refer to a uniquely expressed mode of social life based upon patterns of thinking and acting that reflect overtly and covertly organized feelings and perceptions which are held in common by all the normal members of the community.

As regards the interplay between culture

and personality, the position taken by us can be defined as follows: Certain drives and infantile experiences are common to all human beings though variations in degree and quality occur. Parental values, attitudes and controls which reflect cultural tradition are, by precept and example, implanted in, and incorporated and absorbed by, the ego of the child and form the core of his conscious and unconscious superego. Consequently culture does not only represent the fabric of the ways of living of the society in which we live but it also has its counterpart in our inner world. In line with this argument culture conflict has its battleground in the inner as well as in the outer world.

A still wider vista unfolds if human behavior (normal and abnormal) and any of the areas named are subjected to comparison in contrasting cultures. Because this approach goes beyond the boundaries of one culture, we have called it *transcultural*; its comparative and contrasting aspects have been labelled cross-cultural.

During the last 3 years Dr. Fried and I have been jointly engaged in a transcultural psychiatric study. The aims of this research are to arrive at conclusions regarding which cultural norms make for mental health and which foster the development of mental illness; and by isolating and defining modifiable socio-cultural variables, to work towards prevention, or at least reduction, of mental illness.

SOURCES OF DATA

The data summarized in this paper have come predominantly from correspondence with psychiatrists and social scientists abroad, strategically placed and qualified to be able to give authoritative information. This communication network stretches around the world and has involved over 30 countries.³

¹ Read at the 115th annual meeting of The American Psychiatric Association, Philadelphia, Pa., Apr. 27-May 1, 1959.

² Respectively, Associate Professor of Psychiatry and Assistant Professor of Anthropology, McGill University, Montreal, Can

³ The information thus received was organized in the form of a number of Newsletters (Newsletter—Transcultural Research in Mental Health Problems) sent to our correspondents and available to others interested in the subject.

A SURVEY OF CROSS-CULTURAL MENTAL HEALTH PROBLEMS

Four questions concerning this field of interest which have been raised repeatedly will be taken up successively.

1. ARE THERE ANY SIGNIFICANT DIFFERENCES IN THE PREVALENCE AND INCIDENCE OF MENTAL DISORDERS IN DIFFERENT CULTURES ?

Largely based on rates of mental hospital admissions and hence open to objections regarding their general validity such differences have been reported. For instance mental hospital admissions of schizophrenics according to Ratanakorn(2) amount to 72% in Thailand as against 28.8% in the U.S.S.R.(3) on a survey of 193 Soviet Russian mental institutions. According to several observers, the incidence of depressive psychoses is low among African negroes(5, 6, 7), and among Indonesians(8). The suicide rate is reported high in Japan, Denmark, Switzerland, and in Whites resident in South Africa. It is low in Ireland(9), in African negroes(10), and non-existent in the Bantu. Margetts(11) reporting from Kenya, doubts whether depressions and suicides in Africa are really as rare as is generally believed. According to him "most Africans do not have much of a concept of depression as an illness though they have words for sadness and grief." Rarity of senile psychosis has been noted in Hong Kong (12) and Formosa(13). Also open to doubt is the alleged very low incidence of psychoneuroses in African negroes, Chinese and Indians. It seems conceivable that the scarcity of trained psychiatrists in these countries is such, and the necessity to deal with psychiatric emergencies is so great, that the problem of psychoneurosis, which looms so large in the western world, is of minor importance. The writers from Ireland(9) and Greece(14), in Europe, and an Indian psychiatrist, M. R. Gaitonde(15) in Bombay, are the only ones who report on conversion hysterics in appreciable numbers. Obsessional neuroses have been reported as rare on Formosa(13), in Kuwait(16), and among African negroes(10). The common belief, recently restated by Stainbrook(17) that the high incidence of psychosomatic disorders is one of the doubtful privileges of western civilization is not borne out by Parhad's(16) observa-

tions in Kuwait and by Seguin's(18) and our own observations in Peruvian Indians. Alcoholism is rare on Formosa(13). It constitutes a particularly serious problem in Peru(19) and in the Union of South Africa(10). Sexual perversions have been reported as common in Iran(20), and as rare in Russia(21).

2. ARE THERE ANY MENTAL DISORDERS COMMON IN SOME CULTURES BUT NON-EXISTENT IN OTHERS ?

From what has been said it is evident that the main categories of mental disorders are ubiquitous. Mental disorders confined to certain geographical areas are those due to malnutrition, to malarial and other infections, toxic psychoses, and variants of drug addictions. African specialists have identified what seems to be some mental syndromes indigenous to that continent, e.g. Carother's(4) "frenzied anxiety." Whether this is an organic illness or a functional psychosis is not clear. Only further research on such apparently unique disturbances can prove whether they are cultural variants of known conditions or totally new phenomena.

3. ARE THERE ANY NOSOLOGICAL DIFFERENCES IN THE MANIFESTATIONS OF MENTAL DISEASE ON COMPARISON OF DIFFERENT CULTURES ?

The example of schizophrenia may be given. Observers with psychiatric experience in the East and in the West(22), have noted that hospitalized schizophrenic patients are less aggressive and less violent in India and in Japan than schizophrenics in western mental hospitals. Caudill(23) observed that Japanese schizophrenic patients, more than patients in the United States, maintain contact with other human beings.

Schizophrenia in African natives is said to be quieter and less florid—a poor imitation of European forms(24). Twilight or confusional states, often of short duration, are common. Severe schizophrenics in various stages of deterioration, with marked blunting of affect and poorly organized, autistic thinking, prevail or at least come predominantly under the care of psychiatrists. Most observers agree that the hebephrenic form of schizophrenia is most commonly seen and that the paranoid form

is relatively uncommon. Hallucinations, auditory and visual, are systematized and have a predominantly mythological content. Delusions of being bewitched or poisoned are most common.

4. ARE THERE ANY PSYCHIATRIC SYNDROMES SPECIFIC TO CERTAIN GEOGRAPHICAL AREAS OR CULTURAL CONFINES ?

Such syndromes, to mention just a few, have been described under the names of Koro, Latah, Imu, Arctic hysteria, Youngda-Hte, Hsieh-Ping, Susto and Windigo psychosis.

Patients suffering from *Koro*, a disorder reported from Malaya and Southern China, are suddenly seized by the belief that their penis is shrinking into their abdomen. To forestall such an event which, according to popular belief, would lead to death, elaborate preventive measures are taken, such as clamping the penis into a wooden box or tying a red string around it (12).

Latah has been reported from various parts of the world (among the Malay races, as Imu among the Ainu of North Japan and as Arctic hysteria among Eskimos and Siberian natives). It is usually precipitated by fright, occurs in middle-aged women, and is characterized by a trance-like state with automatic obedience, alternating with motility storms, echolalia and echopraxia (12).

A trance-like state under the name of *Hsieh-Ping* has been reported from Formosa (13). The symptoms during seizures, which last from half an hour to many hours, consist of tremor, disorientation, clouding of consciousness and delirium, often accompanied by visual or auditory hallucinations. An outstanding feature is ancestor identification. Magical and mystical animal transformation states have been reported from Indonesia (8).

Sal y Rosas (25), one of our correspondents from Peru, reports on a condition named *Susto* (magic fright). It is precipitated by a violent fright experience, occurs usually in children and adolescents and is characterized by intense anxiety, hyperexcitability, and a state of depression accompanied by considerable loss of weight. The patients believe that their "soul" has been separated from their body, and has been absorbed and kidnapped by the Earth.

The treatment applied consists of magical acts to recover the fugitive or robbed spirit.

To return to the question raised, it appears that the syndromes described constitute, to some extent, clinical entities, though they are less specific nosologically than is frequently believed. Phenomenological overlap between some of the syndromes described under different names in geographically widely separated areas is noticeable. According to local psychiatric observers, most of the syndromes have been regarded as culture-bound variants of hysteria.

SOME PSYCHOCULTURAL AND SOCIOCULTURAL CONSIDERATIONS

Thus far a brief account has been given of observations which have been made. In appraising their significance, psychocultural as well as sociocultural variables have to be taken into account.

PSYCHOCULTURAL VARIABLES

Obsessional neuroses. The alleged absence of obsessional neuroses in some cultures, e.g. in African negroes (26) and in Chinese (13) could be attributed: to the disinclination of obsessive-compulsives all over the world to consult psychiatrists; to the mitigating effect of lenient early toilet training on sphincter morality development; to externalization of a threatening superego in the form of popular beliefs and superstitions; and to absorption of obsessional defences into culture dictated rituals.

Depression. The rarity of depression, if indeed it is rare, in certain cultures, e.g. among African natives, has been accounted for: by a weak superego formation, by predominance of projective mechanisms and by the prophylactic effect of ritual and ceremonial observances following a death. Contrasting the high incidence of confusional excitement, often combined with homicidal behaviour, and the rarity of depression, P. K. Benedict and Jacks (27) suggest that in non-literate cultures hostility of psychotics is channelled outward, whereas in Euro-American culture hostility is more often directed inward.

Schizophrenia. Divergent views have

been expressed regarding the relevance of Oriental cultures to the incidence of schizophrenia. It has been suggested that the Eastern way of life (a) predisposes to schizophrenia(2) (b) conceals it in prizing and rewarding schizoid trends(28) and (c) safeguards against it by providing outlets for introvert tendencies(29, 30).

Beyond this, it is obvious that the content of schizophrenic delusions is conditioned by culturally patterned orientation and that their paucity or richness reflects the modalities of mental and behavioural activities inherent in diverse cultural systems.

SOCIOCULTURAL VARIABLES

As regards sociocultural variables the effects of detribalization, urbanization, culture change, migration and culture-determined differences in psychotherapy will be briefly dealt with.

1. Observations made in various parts of Africa(31, 7) and in Haiti(32) show that, as rural, backward and tribal native populations enter urban areas, mental disorders increase in frequency and their clinical manifestations approximate those of the European white settlers.

2. There is general agreement that radical culture change is felt by large sections of the affected populations as a stressful experience. A frequent result of stressful experiences of this kind is an increase in antisocial behaviour. However, differing responses to similar experiences have been noted in culturally distinct groups. Thus, in Israel(33), Jewish immigrants from Tunisia have a high rate of delinquency and of other forms of antisocial behaviour whereas Yemenites have a low rate.

Other apparently culture-bound variants of mental phenomena reported in migrants include a high frequency of bronchial asthma in Iraqi Jews migrated to Israel and of generalized, shifting pains in Indians migrating from the Andes to the coastal cities of Peru(18).

3. Crosscultural evidence indicates that differences in culturally based attitudes towards the mentally ill and towards mental hospitals may influence rates of commitment and of release. Irrespective of availability of mental hospitals, there is a high

tolerance in Oriental and African societies for what in the Western world would be considered seriously disturbed behaviour.

Cultural premises influence types of treatment procedures in different cultures. For instance, adherence to traditional systems of values seems to account for the resistance of Japanese psychiatrists to psychoanalysis and their preference for ego-directed forms of psychotherapy founded on established and accepted religious systems. Prominent among these are: Morita-therapy based on Zen Buddhist disciplines and Nishimaru's Confucian based persuasion therapy(34).

Still another aspect of cultural orientation is applied to psychotherapy by Spiegel(35) who showed that the goals of psychotherapy and the therapeutic process as such, are influenced by concordant or discordant cultural values of therapist and patient.

CRITICALLY ASSESSING VALIDITY OF DATA

The general survey given throws into relief the numerous difficulties which beset the student of, and investigator in, the field of transcultural psychiatry, some of which follow.

Variability of the concepts of mental health and illness. While it is difficult enough to agree on what is "normal," "still normal" or "already abnormal" in one's own culture, these difficulties are multiplied if standards of normality and abnormality established in one culture have to be compared with those in an entirely different culture. Application of Western standards of normality by Western psychiatric observers in dealing with primitive societies may result in grave errors regarding the frequency of mental illness owing to ethnocentric orientation and ethnocentric bias.

Moreover, it has been pointed out that historically and geographically disease detection, disease-naming and disease acceptance are conditioned by the prevailing social and cultural systems of medical behaviour(17) i.e. "being sick" is a cultural phenomenon in itself. For instance, shamanism which would be regarded as pathological by us is regarded as normal in the countries in which it is practised and dysmenorrhoea becomes an illness only if the

social system in which the sufferer lives considers having pain with menstrual periods as an illness. As mentioned before, the same argument applies to the absence or presence of depression in primitive societies.

Variability of nomenclature. Visitors from the Far East, accustomed as they are to Kraepelinian diagnostic criteria, are usually amazed by the much wider conception of the term in North America. Similarly, the relatively high figure for incidence of the manic form of manic-depressive psychoses in some cultures has been attributed to the tendency of local psychiatrists to diagnose states of excitement as manic rather than as catatonic excitement or schizo-affective state as undoubtedly many psychiatrists would (17, 27).

Variability of locale of observations. Data on mental illness in primitives, as far as psychiatrists are concerned, have been predominantly obtained from hospitalized patients. Since in native culture, a majority of the patients suffering from mental illness do not seek medical help or are attended by native practitioners, observations based on hospitalized patients deal with a highly selected population. Comparison of observations made in field studies with hospitalized patients is clearly impossible.

Other difficulties encountered in establishing valid comparisons include inadequate training of anthropological observers in psychiatry and inadequate training of psychiatric observers in anthropology, as well as differences in the quality, training and orientation of the psychiatric observers, in the methods of sampling, in the intensity of the investigation, and in the methods of computation of data.

Last but not least, differences in cooperation of the populations studied have to be taken into account. Partly because they mistake the white doctor as the stereotype of the "official" partly because they fear hospitalization, natives on being interviewed are apt to adopt evasive tactics (36) or to fabricate. Africans are known to be great storytellers (11). Moreover when an interview with a preliterate or barely literate person has to be conducted through an interpreter, distortions of meaning will inevitably arise.

SUMMARY AND CONCLUSIONS

There are many ways of viewing the etiology of mental disease. It can be understood as being due to heredity, due to fixation at infantile levels of instinctual development and faulty early object relationships, due to biological dysfunctions and due to influences arising from interpersonal relationships within the society or culture in which an individual lives. None of these viewpoints is "wrong" but each represents a segmental view of a multilateral process.

In the foregoing an attempt has been made to survey our present knowledge regarding the relevance of social and cultural factors to the etiology and treatment of mental illness. In this survey which inevitably had to be incomplete many questions have been raised and few have been answered. It has been shown that the major categories of mental disorders occur ubiquitously, that there is some evidence that they are distributed unevenly, that nosological differences exist between different cultural areas and that differences both in frequency and in nature of clinical manifestations can be related to cultural differences. Methodological difficulties especially of comparative quantitative studies but also of qualitative studies have been pointed out.

THERAPEUTIC RE-ORIENTATION IN SOME DEPRESSIVE STATES : CLINICAL EVALUATION OF A NEW MONO-AMINE OXIDASE INHIBITOR (W-1544-A) (PHENELZINE (NARDIL)¹)²

WILLIAM FURST, M.D., F.A.P.A.³

Humphrey Osmond(1), in discussing historical considerations in "Chemical Concepts of Psychosis" stated, "When you are searching for a needle in a haystack, the knowledge that someone has pricked a finger ought to be encouraging." It would appear that in this era of ataraxics and energizers some investigators have experienced lancing wounds.

In 1939 I was a first year staff psychiatrist at Norristown State Hospital in Pennsylvania. At Dr. A. P. Noyes' weekly diagnostic conference, the following case was presented :

A female, aged 54, hospitalized for 2 years, exhibited marked retarded depression, anergia, insomnia, anorexia, and anhedonia. She had twice tried suicide. Her predominant remark was "I feel dead inside and wish I were dead." Her lips were cracked and her neck showed reddish discoloration. Her tongue was dry. Constipation was extreme. Her ward physician, then in analytic training, offered a diagnosis of Involuntional Melancholia and proceeded to give his psychopathological formulation from the then current Freudian viewpoint. "This patient suffered from penile envy as a child. Having a baby, to her, equalled having a penis. Menstruation meant the capacity to have a baby (or penis). Cessation of menstruation caused an awakening of infantile attitudes concerning castration. Thus involuntional depression unconsciously was related to a disappointment over the lack of a penis." In discussing the case I remarked that the clinical picture was suggestive of the depressive state accompanying pellagra, for which nicotinic acid might be of value. The laughter of my colleagues squelched me. It was then heretical to object to dynamic analytic formulation.

I was then aware of Bleckwenn's(2) report in 1930 on the intravenous use of

sodium amytal in altering affective states. Accordingly, I gave the patient a solution of 3% grains of sodium amytal intravenously. Her response was dramatic. Within 3 minutes she was conversant, describing her intense relief that something could help her. Within 2 hours she again relapsed into her former state. I am sure this reaction has occurred in the experience of many eclectic psychiatrists. Heartened, I prescribed nicotinic acid and she eventually improved. But how did improvement occur? This thought and the sequence of events leading up to it remained with me. The era of electroshock treatment did not obliterate it. Moreover, numerous referrals of depressive psychoses from psychoanalysts who conceded defeat with analytic therapy (and whose patients responded to ECT) served only to heighten my curiosity. Do we really know anything specific about most depressive states other than pure theory or empirical result?

In January 1957, when my attention was directed to iproniazid by Kline, *et al.*(3), the experience of 20 years before sparked my curiosity. Perhaps iproniazid, related to nicotinic acid, was a breakthrough to a more specific understanding of depressive states?

Accordingly, I treated 100 cases of severe depressive syndromes with iproniazid, reporting my results to the Eastern Psychiatric Research Association in October 1957 (4). Approximately 3 out of 4 cases responded as well as, if not better than, to ECT. This experience has been verified by others.

Zeller's(5) contribution that iproniazid inhibited mono-amine oxidase suggested a potential pharmacological understanding for the improvement clinically demonstrable.

Brodie, Spector, and Shore(6), demonstrated the potential importance of the brain "neuro-humors" serotonin and norepinephrine, and their relationship to the enzyme mono-amine oxidase. Iproniazid,

¹ U. S. trade name.

² Read at the 115th annual meeting of The American Psychiatric Association Philadelphia, Pa., Apr. 27-May 1, 1959.

³ Attending Neuropsychiatrist, East Orange General Hospital, East Orange, N. J.

inhibiting mono-amine oxidase, increased available brain nor-epinephrine and serotonin for "normalizing of cerebral activity." Is it likely then that mono-amine oxidase inhibitors act as catalysts in psychological energy exchanges? In depressive syndromes, where anergia is such a dominant symptom, the recall of a basic law of physics, that "energy can neither be created nor destroyed, but may be transformed" seems rational within the conceptual framework of "psychic energizing." Psychiatrists must now give attention to this new parameter and also integrate these concepts with recent neurophysiological data concerning input, brain coding and de-coding, feedback systems and output mechanisms.

While these concepts bring us closer to a psychophysiological understanding of therapeutic effectiveness, there are still many blind spots in the theoretical construction, but for the present, new insights are accumulating in the etiology of "depression." Reflect for a moment on an excerpt from a recent address by Aldous Huxley, entitled "The Final Revolution." Therein he discussed "the social, ethical, and religious implications of the new biochemico-psychological techniques which are making it possible to act *directly* on the human organism rather than, as was the case with earlier revolutions, on the environment with a hope of changing behavior *indirectly*."

NOSOLOGY

Evaluation of mood disorders requires attention to the outstanding manifestation, depression. Glibly we talk of the treatment of depression, frequently using the symp-

tom and the syndrome interchangeably.

When we communicate within the framework of reference of "depression," exactly what do we mean? Much confusion exists. Garmany(7) studied 525 depressives divided into 3 categories:

A. In the manic-depressive endogenous type, depression comes from within, meaning the same as idiopathic, *i.e.*, one does not know why it happens but that it is a disease entity.

B. In the involutional depression, the age range is usually menopausal to old age. There is a pre-morbid compulsive perfectionistic personality. No previous attacks have occurred and usually hypochondriasis and agitation have been associated.

C. In the reactive type, there is a progressive reaction to events and thus it is not considered as a disease entity.

Garmany concludes that the differentiation between these types is an unreal one and that their distinction is merely a matter of quantity rather than quality of the disease.

I take issue with these conclusions since this traditional concept maintaining the influence of primary situational factors and/or intra-psychic conflict denies the psychopharmacologic and physiologic understandings which are slowly accumulating. A more meaningful nosological classification of depressive states is long overdue.

W-1544-A (PHENELZINE) (NARDIL)

Due to the hepatotoxicity of iproniazid, intensive search has been underway for substitute effective analogues. In September 1958 the experimental compound W-1544-A

FIG. 1

STRUCTURAL RELATION OF NICOTINIC ACID AND IPRONIAZID

was made available to me for clinical screening. The structural formula is :

B-phenethylhydrazine

FIG. 2

CHEMICAL CONFIGURATION OF W-1544-A

Phenelzine (W-1544-A) in common with iproniazid, J.B. 516 (Catron), and numerous other drugs, is a potent mono-amine oxidase inhibitor. Experimentally in vivo animal testing demonstrates that W-1544-A effects approximately 5 times more mono-amine oxidase inhibition than iproniazid. Furthermore, 1/5 the dose of W-1544-A increases brain serotonin in experimental animals higher than iproniazid (8). It is of interest to note the structural similarity of W-1544-A and iproniazid to other sympathomimetic drugs, *i.e.*, ephe-drine, nor-epinephrine, and amphetamine.

W-1544-A in its action resembles sympathomimetic amines. It has a prolonged

effect on mono-amine oxidase and is cumulative in action on repeated administration.

TEST SAMPLE

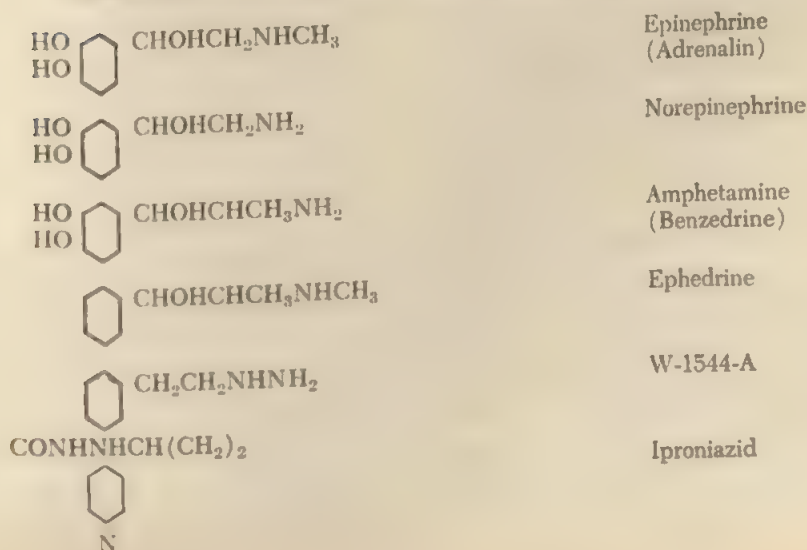

In this experiment, non-hospitalized patients were carefully selected from private practice primarily for the clinical picture of the depressive syndrome characterized by anergia, anorexia, anhedonia, weight loss, insomnia, and depression. Situational factors were either minimal or absent. Supportive psychotherapy was minimal and essentially of the repressive rather than expressive type.

DOSAGE

In this screening study oral dosage ranged from 60 mg. to 90 mg. daily in divided doses. If response was obtained within one week or less, the dosage was gradually adjusted downward. Pyridoxine 25 mg. daily was routinely used on the theory that this vitamin has prophylactic effect on the induced pyridoxine deficiency. Maintenance doses of 6 mg. daily of W-1544-A were eventually achieved in about 4 to 6 weeks and continued 2 to 3 months or longer.

FIG. 3

CHEMICAL STRUCTURAL RELATIONSHIP BETWEEN ENERGIZING DRUGS

SIDE EFFECTS

On this regimen there have been relatively few adverse effects noted. Most of the symptom complaints could hardly be distinguished from depressive concomitants. Those observed were:

SYMPTOM	<i>Probably due to depressive effect</i>	<i>Probably due to drug effect</i>
Headache	6	0
Constipation	2	3
Dizziness	3	2
Heartburn and bloating	3	2
Increased agitation	2	2
Drowsiness	1	3
Nausea	3	0
Insomnia	4	0
Weakness	0	2
Weight loss	1	1
Bad taste, dryness or burning of mouth	3	1
Blurred vision	1	1
Generalized paresthesias	1	0
Drowsiness and head fullness on sympathomimetic drug	1	0

FIG. 4

SIDE EFFECTS DUE TO W-1544-A

CONTRAINDICATIONS

Phenelzine has mild drug potentiations with sedatives and narcotics. In one instance incompatibility with Wyamine, producing severe headaches, was noted. Dental extraction with adrenalin-novocaine local anesthesia may have produced adverse blood pressure effects. As with all drugs of the mono-amine oxidase inhibiting group,

previous hepatorenal disease is a relative contraindication unless carefully followed with appropriate laboratory studies. No incompatibility between phenelzine and electrotherapy has been noted in 10 treated patients.

COMPARISON WITH IPRONIAZID

Extensive experience with iproniazid permits comparison as follows:

	IPRONIAZID	W-1544-A
Drug potency	+++	++
Hypotension	++	=
Appetite stimulant	+++	+
Weight gain	++	±
Edema	+	0
Libido	±	0
Insomnia	+	±
Jaundice	+	0
Tremors	±	0
Constipation	++	±
Paresthesias	±	±
Heartburn and bloating	±	0
Headache and/or dizziness	+	0

FIG. 6

COMPARISON EFFECTS OF IPRONIAZID AND W-1544-A

LABORATORY DATA

Pre-test urinalysis, C.B.C., alkaline phosphatase, thymol turbidity, and cephalin flocculation tests were compared with similar findings determined after the second month of ingestion. To date no significant abnormalities have been detected in 30 cases studied in this series.

FIG. 5

THERAPEUTIC RESULTS WITH W-1544-A

Total number of patients treated	50	
Number of patients completing more than 4 weeks treatment	36	
Number of patients approaching remission	25	
Number of patients unchanged	11	
Number of patients unimproved, not completed more than 4 weeks of treatment	14	
% Remissions of patients completing more than 4 weeks treatment		69%
% Patients unchanged who completed more than 4 weeks treatment		31%
% of remissions in total series		50%

SUMMARY

A re-orientation to theory and therapy of some depressive states is slowly coming into sharper focus. The sequence of events developing from the response of a depressed patient to nicotinic acid and its relation to iproniazid is presented. Psychic energizers, mono-amine oxidase inhibitors, serotonin, and nor-epinephrine may have etiologic relationship in depressive disorders. Neurophysiological findings must also be integrated with psychopharmacological researches. A more specific nosological re-classification to recognize that involuntional melancholia, manic-depressive states, and reactive depression may vary qualitatively rather than quantitatively is in order. Clinical experience with phenelzine (W-1544-A), a new mono-amine oxidase inhibitor, is presented as to drug characteristics, dosage, side effects, therapeutic effect, and comparability with iproniazid. In a preliminary screening at the private practice level, 69% of 36 patients who completed more than 4 weeks of treatment with W-1544-A showed remission from endogenous depressive states.

CONCLUSIONS

1. Phenelzine (W-1544-A) is a potent anti-depressant drug approaching the therapeutic effectiveness of iproniazid.

2. In a screening test with severely depressed ambulatory private patients, no jaundice, abnormal weight gain, or significant hypotension was noted with W-1544-A. This is in sharp contrast to the use of iproniazid administered under comparable conditions and similar dosage.

3. W-1544-A is a further advance in the psychopharmacologic, theoretical, and therapeutic re-orientation to depressive illness.

DISCUSSION

DOUGLAS GOLDMAN, M.D. (Cincinnati, Ohio).—Dr. Furst's paper is concerned with two properly related topics: first, therapeutic re-orientation in some depressive states, and second, clinical evaluation of a new mono-amine oxidase inhibitor. From long experience in the treatment of depression in private patients and in state hospital patients, and from strong personal bias in favor of organic orientation in psychiatry as well as in favor of physical and pharmacologic treatment methods, I anticipated a great deal of satisfaction in the opportunity to study the material in this paper. The cause of organic understanding in psychiatry, however, will not be promoted by any but the most carefully documented data whether in relation to theoretic formulation or evaluation of new treatment methods. I am in complete agreement with Dr. Furst in his rejection of any analytic formulation as an explanation of the etiology of depression, but the attempt to relate the occurrence of pellagra in 1939 when it was all too common in state hospitals to the etiology of depression of long standing (which indeed might have been the cause of the pellagra), and relating the therapeutic effects of nicotinic acid with those of any amine-oxidase inhibitor of whatever chemical structure, is so strained that it represents a close approach to a psychiatric, chemical, and pharmacologic non-sequitur.

It is certainly evident to most of us that the concept of depression requires clarification, but there is as yet no warrant for criticizing Garmany's division of depressive patients into 3 categories: endogenous, involuntional and reactive, on the basis of

pharmacologic or physiologic understanding. Our knowledge, in spite of a great deal of effort on the part of many individuals and groups of careful workers, has not progressed to the point of clarifying and re-organizing clinical concepts. It may well be that physical and pharmacologic treatment methods are effective in the treatment of depression, but empiricism, however gratifying and practical, is no substitute for understanding based upon knowledge of etiology, anatomy and physiology. We are, in the understanding of the symptom, depression, at a level similar to that of the clinician dealing with fever prior to the discoveries of micro-biology and without the understanding of neuro-physiologic control of the temperature mechanism.

W-1544-A is a potent pharmacologic and therapeutic agent with properties similar to those of other mono-amine oxidase inhibiting hydrazides. We have used the material in a variety of state hospital patients with various depressive manifestations, occurring in a number of different clinical categories. We have treated 45 patients with W-1544-A over a period of 1 to 11 months as part of a larger project involving a number of anti-depressant drugs, both amine-oxidase inhibitors and substances without this property. In such a study of the effect of anti-depressant drugs, the concept of "psychic energy," is revealed as a useless mis-application of a good scientific word. As Dr. Brodie pointed out in a previous discussion along this line, the word "energy" refers to a measurable physical property that can be expressed in ergs.

Anti-depressant drugs have certain specific clinical properties that distinguish them from stimulants and from those anti-psychotic substances rather improperly called ataractics. All kinds of depression are not relieved by these drugs. Schizophrenic withdrawal, disappointment and grief do not respond. Only the specific kind of illness recognized by every psychiatrist as depressive, whether considered "endo-

genous," "dysphoric," or otherwise qualified, responds brilliantly to the use of the anti-depressant drugs. These drugs are not all mono-amine oxidase inhibitors. Other important properties of these drugs manifested clinically are the activation of schizophrenic symptoms in schizophrenic patients only, and the "over-shooting" of therapeutic effect with production of active manic manifestations in those depressive individuals who are susceptible to them. W-1544-A has these properties *par excellence* in common with iproniazid, Tofranil and other substances studied. These drugs therefore require reasonably close attention to the patient particularly in the earlier period of treatment, within the first 6 to 10 weeks. We have not seen jaundice with any of the anti-depressant drugs we have studied, and this includes 250 patients treated with iproniazid. W-1544-A remains innocent in this respect also. However, we have studied, over a long period, blood pressure fluctuations in 37 patients. Twenty-one of these, well over half, showed a drop of at least 20 mm. in systolic blood pressure and 8, more than 20%, showed a drop to 90 mm. or below. This is comparable to observations with iproniazid. It is, therefore, our considered opinion that blood pressure must be closely observed in the first 6 weeks of treatment, at least, and that patients who cannot be relied upon for co-operation should be omitted from study with this drug.

We have also seen two instances of hyperkinetic excitement produced by W-1544-A. This effect, also observed with other anti-depressant drugs is not to be confused with over-stimulation. It subsides promptly on the use of an effective phenothiazine, such as triflupromazine or perphenazine, given parenterally by preference under such circumstances.

We consider W-1544-A an extremely potent and useful anti-depressant agent requiring mature clinical skill in its use. It represents a significant addition to the list of drugs of psychotherapeutic value.

CONSIDERATIONS IN DETERMINING A MODEL FOR THE MENTAL HOSPITAL¹

MORRIS S. SCHWARTZ, Ph.D., AND CHARLOTTE GREEN SCHWARTZ, M.A.²

The controversy over the size of the mental hospital is but one of the many issues about the organization of inpatient facilities for mental patients. Other issues deal with the theoretical orientation that should guide such a facility or the treatment it should use. Some practitioners maintain that the basic orientation should be somatic; others hold that it should be psycho-social; still others attempt some combination of orientations. Drugs, individual psychotherapy, and milieu therapy are each advocated as the primary form of treatment.

It seems to us that a basic problem related to these specific issues concerns the model that is appropriate for an inpatient facility. That is, what plan or blueprint should serve as a guide for developing the form and social organization of a treatment institution for mental patients? Should it resemble a general hospital, a school, or a set of family units? Before such a model can be developed, certain considerations must be faced. In this paper, we would like to direct attention to what we feel are basic considerations in devising a model that would have potentialities for effectively contributing to the improvement of patients. We recognize that more than one model may be required. We are not concerned here with describing the kinds of models suitable for different types of patients, but with some considerations that have to be taken into account in arriving at such models.

THE FEASIBLE AND THE DESIRABLE INSTITUTION

In conceptualizing a model for an inpatient facility, it is important to consider both the institution that is feasible and the one that is desirable. Focusing upon the feasible directs attention to what can come about in the immediate future; considering

the desirable can help establish long-term goals that, in turn, will affect decisions made in the present. A basic difficulty in the discussions of inpatient facilities is the frequent failure to distinguish between the feasible and the desirable. Practitioners often fail to make clear whether they are referring to what they believe *should be* or what they think *can be* achieved in the immediate future. Thus, in the present controversy over the size of the facility, do some practitioners support the idea of the large state mental hospital because they think it is the only feasible pattern at present while their opponents attack it because they believe the conventional state hospital is undesirable? If the participants in such discussions stated from which of these standpoints they were speaking, the issues might be clarified and fruitless talking past each other might be avoided.

THE THEORETICAL ORIENTATION TOWARD MENTAL ILLNESS AND ITS TREATMENT

Another important set of considerations is the practitioner's conceptions of mental illness and its treatment. Often kept implicit, these conceptions partly determine his ideas about what patient needs are, how these needs can be met, and what can be done to facilitate patients' improvement.

A different type of facility may be required if the mental illness is seen as a function of faulty interpersonal relations to be treated via interpersonal means than if it is conceived of as an organic disturbance for which somatic therapies are indicated. In the former case, the primary orientation would be on organizing, directing, and utilizing interpersonal relations for patient benefit. In the latter, the primary function of the social organization would be to facilitate the administration of somatic therapies. If the conception of illness encompasses both the interpersonal and the somatic, the facility would need to be different from one based exclusively on either conception.

It seems to us that if practitioners are

¹ Read at the 115th annual meeting of The American Psychiatric Association, Philadelphia, Pa., Apr. 27-May 1, 1959.

² 105 Channing Rd., Watertown 72, Mass.

to develop a rational plan, they must make explicit their conceptions of mental illness and its treatment, the bases for their ideas, and the implications of these conceptions for the form and organization of an inpatient facility. From such specification they can begin to draw the connections between theory and practice and develop the outlines of a facility accordingly.

THE PURPOSES AND INTERESTS PRACTITIONERS WOULD LIKE THE FACILITY TO PURSUE

The goals of the facility must be considered in planning it. Although the stated goals may be to treat patients and to help them return to society, a mental institution usually has other goals, such as: protecting society against deviants, protecting patients against themselves and each other, and caring for certain persons unable to care for themselves. These goals must be clarified and related to one another. This should help the practitioner discover the social structure most suitable for achieving the primary objectives.

Ordinarily, the hierarchy of purposes is not clearly specified, and practitioners try to pursue a number of purposes simultaneously without giving primacy to any one. This lack of clarification of the facility's purpose and of the conditions under which one or another purpose takes primacy makes it difficult to discover the kind of social structure that will most adequately carry out these purposes.

For example, if the major purpose is to re-educate and re-socialize patients, the practitioner must specify the kinds of social situations to which patients will return and the nature of the problems they will face. He then can begin systematically preparing patients for the roles they will assume outside the institution. This would mean that the form and structure of the facility must be oriented to the processes of unlearning and relearning social behavior and to guiding patients through a series of graded tasks and learning situations until they graduate to the outside. If the practitioner takes the primacy of this purpose seriously, he cannot just add the re-education idea onto the operation of the conventional mental hospital. The entire organization of the facility would have to revolve around this conception, and other elements

would be subservient to this purpose.

On the other hand, if the primary purpose is to protect society against the patient, another type of social organization would be more appropriate, directed toward maintaining control, surveillance, and reducing the risks of patient misbehavior and destructiveness.

Usually it is necessary to work out a balance between a number of different purposes. For a multi-purposed institution, it is important to be clear about the conditions under which one purpose takes precedence over another.

Furthermore, it is important for the practitioner to specify the effects he would like to have on patients as a result of their stay in the facility, in terms of cure, reorganization of personality, improvement, alleviation of symptoms, prevention of further deterioration and the like. Practitioners also hope their patients will attain a more adequate degree of functioning in social roles or develop the ability to get along outside a mental institution.

While some practitioners believe it is important to make treatment objectives explicit, they often fail to make explicit the social objectives that they hold for patients. Even less frequently do they consider the connection between their objectives for patients and the way the facility needs to be organized to attain these objectives.

We would maintain that the practitioner's treatment objectives imply a set of social values. These values become embodied in inpatient facilities. Some institutions, for example, largely reflect the values of having patients "get along with people," abide by institutional rules and regulations, and be cooperative members of hospital society. Many of the institution's forms are directed toward insuring patient conformity.

But if a practitioner values individuality and uniqueness in patients, he would have to develop a structure that would minimize restrictiveness on patient behavior and would encourage spontaneity. The two social structures would necessarily differ.

But whatever the purpose or purposes and whatever the specific treatment objectives and social values for patients, it is

necessary that each be made explicit in order to evolve a model that can meet these ends effectively.

SUMMARY

In this paper, we have discussed what we consider to be a basic problem in the field of inpatient care: the relative lack of exploration and analysis of the considerations basic to developing a model for an inpatient facility. We have suggested 3 considerations that we feel are important in

such analysis: the feasible and the desirable institution, the theoretical orientation toward mental illness and its treatment, and the purposes and interests practitioners would like the facility to pursue.

It is our conviction that if practitioners explore the implications of this kind of analysis, they may be able to formulate more adequate models for inpatient facilities and thus achieve their central objective of contributing more effectively to patient welfare.

A PSYCHIATRIC STUDY OF CHECK OFFENDERS¹

JOHN M. MACDONALD, M.D.²

Check crimes are among the leading causes for commitment to penal institutions and probably result in greater financial loss to the community than any other form of crime. It has been estimated that check forgery costs the United States \$535 million each year(1). The armed robber receives more publicity than the check offender yet the latter is far more successful in his depredations. The pen is indeed mightier than the sword.

Check offenses include signing the name of another person or of a fictitious person, altering the value of a check and writing a check with the knowledge that there are insufficient funds in the bank to cover it. Legal terms for check crimes include forgery, confidence game, no account checks and short checks. A gullible public, difficulty in detecting the offender, and the reluctance of some victims to prosecute contribute to the problems of prevention.

The 300 subjects of this study include mental hospital patients with a history of check offenses, penitentiary inmates and check offenders referred by the courts for psychiatric examination. Although the group is not a statistically representative cross section of the check offender population, it nevertheless includes a wide range of check offenders. Recidivist check offenders may be classified, according to their pattern of criminal behavior, as skilled and unskilled bogus check writers, check thieves, "pushers" and short check writers. Occasional check offenders and psychotic check writers are considered separately.

The skilled bogus check writer plans his check passing carefully, limits it to a brief period in a large town and then moves quickly to another state where he repeats his offenses when his funds are exhausted. The checks are printed with the title of a state or city government, a widely known or

a nonexistent company. In the latter case a bank account may be opened but only a small deposit is made. The check may be labelled payroll and the value, which is printed with a protectograph, is for an irregular amount such as \$88.72 to give the appearance of a payroll deduction for income tax. A large number of checks are passed late Friday afternoon and Saturday. When the bank discovers the fraud the following Monday, the check writer is already in another state.

When detected he seldom contests the charges and rarely enters a plea of insanity. A minority are extremely successful in evading prosecution by jumping bond or by simulating insanity. The skilled bogus check writer is usually of above average intelligence, between 25 and 40 years of age, and confident in his bearing. There may be a lodge emblem or Rotary Club badge in the lapel of his coat. He is well dressed, avoids flashy clothes and usually operates alone or with a female partner. In his youth, he may have committed other crimes, but now confines himself to check passing.

The skilled bogus check writer is often very successful in his criminal behavior. One offender passed bogus checks amounting to approximately \$55,000 in 28 states during an 18 month period. At the time of his arrest he had in his apartment, 172 completed checks, totaling over \$16,000 as well as 57 Selective Service cards and assorted identification cards(2). The following case history is given as an example of this type of offender.

Case 1. AB, a good looking, 30-year-old married man of superior intelligence (I.Q. 138) had a somewhat checkered career which included car theft at 15 years. He was earning a high income at the time of his induction into the Army during World War II. Unwilling to change his mode of living to suit his Army pay, he began writing bad checks which were at first covered by his parents. He soon deserted from the Army and for many years he was so successful as a checkwriter that he was able to hire a private tutor for his children.

¹ Read at the 115th annual meeting of The American Psychiatric Association, Philadelphia, Pa., Apr. 27-May 1, 1959.

² Assistant Professor of Psychiatry, University of Colorado School of Medicine; Assistant Medical Director, Colorado Psychopathic Hospital, Denver, Col.

No crimes were committed in his home town where he lived the life of a man of means. When necessary he would fly to a distant town, get a non-existent company with Dunn and B. Street as well as with a state or municipal agency, establish an office and obtain a telephone listing. Following publication of a new telephone directory, he would return, open a bank account and pass many checks over a weekend. Eventually, he became too ambitious and this led to his downfall.

He opened 2 offices in Denver. In one office a telephone machine gave a recorded announcement that the manager was out and a message should be left. He operated from the other office and referred awkward inquirers to the "manager." In a newspaper advertisement, he offered temporary employment at good pay for persons with college or business training. It was stated that veterans would be given preferential consideration. Prospective employees were required to complete an application form listing previous employment record. He was careful not to hire "obvious characters I wouldn't cash a check for if it was solid gold."

The 40 persons selected for employment were told that he was making a secret customer survey to determine the effort being made by appliance retailers to sell General Electric products as opposed to those of rival firms. They were each given checks for \$150 bearing the G. E. trademark with the words "Rocky Mountain Radio Company" and told to purchase not more than one small electrical appliance. The 4 employees who returned the best reports were promised permanent employment with General Electric as district supervisors. As security for return of the balance on the checks, they were required to leave adequate identification. One of his employees, a former policeman, became suspicious and when the bank president's Saturday afternoon golf was interrupted to check the amount in deposit, the fraud was discovered. AB was particularly irked by the employee's failure to mention his former employment as a police officer in his application form.

The unskilled bogus check writer seldom demonstrates the careful planning, ingenuity and resourcefulness of the skilled offender. He tends to repeat his offenses over a long period of time in the same locality and writes personal rather than business checks. The name of a former employer, acquaintance or fictitious person is used although not infrequently he signs his own

name, either as payer or payee. The checks are for small amounts and in the case of addicts are used to purchase alcohol or drugs. Many of these offenders are sociopaths, alcoholics or drug addicts.

Frequently upon arrest a plea of insanity is made. In support of this plea the suspect may claim that he had money when he wrote the checks and that the checks were written to buy golf balls for which he has no use as he does not play golf. Inquiry will show that the money was small in amount or not readily available and that the golf balls were purchased to persuade a storekeeper to cash his check. Further complaint is made that he must be crazy to write his own name on the checks and to continue such offenses despite repeated imprisonment. He adds, correctly, that he will get into trouble again if sent to prison and requests treatment in a mental hospital. Other suspects claim amnesia and give a history of blackouts following head injury. Usually, the amnesia is simulated or it originated in alcohol, the head injury was slight and the blackouts are not epileptic attacks.

Check thieves specialize in the theft of completed checks, blank checks, money orders, travelers checks and protectographs from business firms, drugstores and mailboxes. They may cash these checks themselves or more commonly employ "pushers" to cash the checks for a small commission. "Pushers" are other criminals, skid row residents or unsuspecting casual acquaintances. The checks are passed in taverns, stores or in supermarkets where certain items such as oatmeal and baby food are purchased to give an impression of respectability. A mimeographed "Check Passers Manual" found on a West Coast offender included hints on disguising handwriting, voice and appearance. The manual suggested that women should use padding and maternity clothing to facilitate both disguise and acceptance of credentials.

Short check writers habitually write checks on their personal accounts with the knowledge that there are insufficient funds in their accounts. This group includes "weekend borrowers" who cash checks on Saturdays with the intention of covering them early the following week. The loss

of time and money on the part of merchants trying to collect on these checks is considerable. The banks do not honor these checks and return them to the cashier. Nevertheless, many banks do not close such accounts until a number of insufficient fund checks have been passed. Criminal charges are often withdrawn by the complaining business firm on payment being made. In this manner the District Attorney's office is used as a collection agency, a practice which seldom meets with official approval.

Occasional check offenders include burglars who do not specialize in the theft of checks, but may steal them along with other items in a burglary. Other criminals may indulge in a single check writing spree but not continue this form of crime. Another occasional check offender is the young sociopath who takes a perverse delight in adding to the risk of detection by writing a check on the East Bank of the Mississippi, or by signing an improbable or insulting name such as U. R. Stung, U. R. Stuck, B. Short or the trade name of the gasoline sold by the service station where the check is being cashed. A new tenant in an apartment house may be tempted to break the law by the arrival in the mail of a check for the previous tenant.

Relatively few check offenders are legally insane. Of 30 legally insane check offenders, 12 suffered from organic brain disease, 10 from schizophrenia and 8 from the manic phase of manic-depressive psychosis. Checks passed by a confused person, suffering from the degenerative changes of old age, are usually honored by the family and criminal prosecution is waived upon the understanding that the patient will be committed to a mental hospital by the civil courts. In some cases of chronic organic brain disease, secondary to alcoholism, the check offenses may have occurred prior to, as well as after the onset of psychosis. Almost 50% of the schizophrenic and manic patients in this study were hospitalized under civil procedures and criminal charges were not filed. Curiously, the manic patient, despite his unusual behavior, is often not recognized as a sick person. Thus one manic patient purchased 6 radios and all the TV sets in a store and his check was accepted without question. An-

other patient, a laborer, wrote over 40 checks totaling \$100,000 in 3 days for purchases which included a new truck. He was not hospitalized until he gave his wife a check for \$30,000.

Police officers familiar with this crime claim that recidivist check offenders show a close resemblance to one another in their personality structure. Study of the clinical records of nonpsychotic recidivist check offenders did not however permit delineation of a typical personality profile. There was, however, a high incidence of sociopathic personality, passive-aggressive personality and chronic alcoholism. Eighty-nine, or 59%, of 150 consecutive offenders examined for the courts were chronic alcoholics.

A wide range of intelligence is found among check offenders. The present group included 6 mental defectives. One man with an I.Q. of 47, who was unable to read or write apart from his own signature, endorsed a bogus check on the instruction of a tavern friend. Another mental defective, explaining that he could not write, endorsed a stolen check with an X sign. The highest I.Q. was 140. In a group of 50 persons tested out of 56 consecutive admissions, 42% had an I.Q. higher than 110, as compared with 25% in the general population (Wechsler Adult Intelligence Scale). This is statistically significant as there is less than one chance in a 100 that this could have occurred by chance. Eight percent had an I.Q. above 130, compared with 2.2% in the general population.

Although many check offenders confine themselves to this one crime, there is usually a history of convictions for other crimes, particularly auto theft in their earlier years. In the present group other offenses ranged from impersonation of an officer, sex crimes and arson to armed robbery, assault, kidnapping and murder. The plane bomber, Graham, who caused the loss of 44 lives, was on probation for check offenses involving over \$4,500 at the time of his arrest. The repeated check offender seldom carries a gun and rarely commits assault.

He gives a variety of explanations for his criminal behavior: "Pressure of debts; family sickness; in-law trouble; divorce; blackmail; threats of physical violence; I

just wanted to have a good time for once ; I never write checks when I'm not drinking." Such statements do not provide an adequate explanation of the wayward behavior. Frequently the money obtained is squandered recklessly. One offender gave \$20 to a blind man, another was so popular with taxi drivers because of his generous tips that they would fight for his custom ; not a few gamble away their proceeds.

A deep seated feeling of insecurity which is assuaged by the purchase of friends or by the demonstration of affluence is one etiological factor. Schur suggests that the assertion of power over the victim may be as important to the swindler (though perhaps not on the conscious level) as is obtaining the sought after money or property (5). Every deception, every imposture is an assumption of power. The person deceived is reduced in stature, symbolically nullified, while the imposter is temporarily powerful, even greater than if he were the real thing(3).

The incurably optimistic overindulged oral character like Mr. Micawber is always expecting something to turn up. "I have signed checks because I was sure my financial position would take a turn for the better before they were due for presentation." The emotionally deprived offender will often commit his crime following rejection by parents or wife. One such offender passed bogus checks only during his wife's pregnancies, when she was unable to meet his excessive needs for dependency gratification. The crime provided symbolic gratification of his unfulfilled needs.

A hostile component in the crime is seen in the offender who writes a bogus check for the purpose of revenge. One patient embarrassed his wealthy father by cashing bogus checks only in stores owned by his father's business acquaintances. Offenders who are unable to express their hostility openly do so indirectly by swindling the victim. A self-destructive component in the crime is apparent in some cases. A patient who showed a need for punishment asked, "Why do I pull a life sentence on the installment plan?"

Parental contribution to the criminal behavior is seen in the offender whose fa-

ther was indignant not at the legal transgression, but at the failure to avoid detection. A widow provided false alibis and always paid the court fines imposed on her son. She would hug and kiss him whenever he was detected in another offense and the extent of her reprimand was the complaint "You should have told me." She was very dependent on her son and she complained that he only showed her affection when he was in trouble. She feared that successful treatment would result in loss of his affection and although she requested psychiatric treatment for him she effectively sabotaged it.

The crime provocative function of the victim deserves mention. Many small businessmen are less cautious in accepting checks when excessive profit is in sight. La Rochefoucauld's statement is pertinent, "One is never so close to being deceived as when one wishes to deceive." The laxity of some firms is remarkable. Checks without signature, employee's earning statements, the negative photostatic copy of a government check, and obvious forgeries have been cashed without hesitation. A 14-year-old youth endorsed an old age pension check and received immediate payment. A 52-year-old man used a high school identity card without arousing suspicion.

Check forgery is one of the easiest crimes to commit and there is no physical danger. The need for greater scrutiny of all checks to reduce the incidence of check crimes is obvious. Check passers avoid stores with cameras which photograph simultaneously the person offering the check, his identification papers and the check itself. Educational programs provided by the Better Business Bureau or similar organizations have been of value in alerting shopkeepers to simple preventive measures. Check alerts over the radio or by telephone publicize the theft of printed checks and discourage "pushers."

The deterrent value of punishment, whatever that may be, is weakened whenever there is a good chance of avoiding detection. The larger communities can well afford a police check squad specially trained to detect check offenders. It may cost more than \$1,000 to prosecute a check crime involving \$50 and courts in small communi-

ties are sometimes reluctant to prosecute because of the expense. Certainly the cost of extradition from a distant state, jury trial and possible psychiatric examination in the event of an insanity plea may prove a heavy financial burden, but in the long run it may be cheaper than failure to prosecute. Victims, especially banks and lawyers are sometimes unwilling to prosecute for fear of adverse publicity, resulting from exposure of their negligent business practices.

The failure of imprisonment to effect reformation of the check offender is reflected in the prison slang, "Once a paperhanger always a paperhanger." There is a need for more specialized penal institutions, similar to the Patuxent Institution (Maryland) and the Vacaville Medical Facility (California), where suitable offenders may be given psychiatric treatment while under indeterminate sentence.

Check offenders, prior to sentencing, often show considerable motivation for treatment. If probation is granted there is, almost invariably, a rapid loss of interest

in treatment combined with an expression of confidence for the future. It is imperative that regular attendance for outpatient treatment should be made a condition of probation. As Schmideberg emphasizes, therapists must accept the unflattering fact that offenders usually see them initially only as an alternative to prison. The therapist must try to convert this enforced relation into a genuine one which can then be used to socialize the patient. Success in therapy depends upon making this conversion(4). The period immediately following release from custody is crucial and the psychiatrist should keep in frequent touch with his patient in order to forestall further offenses.

ENFORCED RESTRICTION OF COMMUNICATION, ITS IMPLICATIONS FOR THE EMOTIONAL AND INTELLECTUAL DEVELOPMENT OF THE DEAF CHILD¹

ROBERT L. SHAROFF, M.D.²

This paper deals with the enforced restriction of communication of deaf children in regard to use of signs, as practiced in some oral schools for the deaf. Questions are raised as to what effect such restriction may be expected to have on the development of the deaf child.

In 1815, several gentlemen of Hartford, Connecticut, headed by Dr. Cogswell, who had a deaf daughter, became interested in the establishment of a school for the deaf in this country. The Rev. Thomas H. Gallaudet had shown some interest in the work and made experimental efforts in teaching Alice Cogswell. These gentlemen resolved to send Gallaudet abroad to study methods there by way of preparation for starting the school they had in mind.

Gallaudet, while in France, learned the sign language and an improved form of the alphabet as modified by the Spanish, and with a few slight changes this was adopted by him when he opened the first permanent school for the deaf in America at Hartford.

As time went on and more efforts were made to educate the deaf, attempts were made to teach the deaf to talk. It was found that the deaf could be taught, with considerable variation in the degree of proficiency, to read lips and to understand what was being said to them, and then to speak and answer with the spoken word rather than with signs. The enthusiasm for teaching oral speech increased in time and in some instances it seemed that this became the goal in itself, as far as the deaf child was concerned, rather than the means of helping him mature to his or her greatest capacities. The consequence was that some schools for the deaf teaching oral speech, prohibited parents from communicating with their deaf child by sign and prohibited

deaf children from communicating among themselves by signs. All communication had to be oral. It is this phenomenon that is being questioned in the present paper: the enforced restriction of communication of the deaf through sign language.

Three questions raised relate to: first, the possible effect of such restriction on the parent-child relationship; second, the effect of such restriction on the deaf child's attempts to communicate with his deaf peers; third, the effect on the intellectual development of the deaf child where the earliest form of symbolization is denied him.

With all children, the earliest forms of communication are through bodily contacts and gestures. Later on, in the hearing child, sound and voice begin gradually to replace gestures. There is no abrupt change, however, and all through life to a greater or lesser degree gestures continue to play an auxiliary role in communication among the hearing. However, in the case of the deaf child, the development is different. Up to a certain stage communication with the deaf child is exactly the same as communication with the hearing child. At one point, varying with the individual child, when it is learned that the child is deaf, where there are in certain areas facilities for his education, the parents are immediately told that all gesturing (signing) must now cease. All communication with the child must be made through speech. The parents are told, "talk, talk, talk all the time." What can such an abrupt inexplicable change mean to a child who is suddenly deprived, for no apparent reason, of all his previous methods of communicating and for a long time is given very little to replace them?

For a considerable time now, the word "rejection" has come to play a very important part in psychiatric literature in attempting to explain the vicissitudes the growing child must cope with in his rela-

¹ Read at the 115th annual meeting of The American Psychiatric Association, Philadelphia, Pa., April 27-May 1, 1959.

² 2 W. 88 St., New York 24, N. Y.

tion to his parents. How great a rejection is it for the child who suddenly finds all his attempts to communicate with his parents suddenly denied him? At the same time the parents apparently stop making any attempt to communicate with the child in a manner familiar to him. Recently, through the work of Ruesch and Bateson(1) problems of communication and its importance in the developing individual have been brought to the foreground. What can it mean to a child who suddenly finds himself cut off from communication with a person or persons to whom he looks for his security and survival? The psychiatric literature has very little concerning either the normal or pathological development of the deaf child. None of the standard textbooks on psychiatry has any description of the emotional development of the congenitally deaf child. There have been sporadic attempts to pick out isolated problems of the deaf. We, therefore, cannot speak with any degree of accuracy of how the handicap of deafness affect the emotional or intellectual development of the child. Only recently have such large scale studies been undertaken as that at Psychiatric Institute in New York. However, I think we can project that by suddenly depriving the deaf child of its earliest and most natural means of communication we are laying the groundwork for future neurotic disturbances.

Ruesch & Kees(2) say :

In the first year of life expression necessarily must occur through non-verbal means. The child literally speaks with his whole body. Difficulties arise when parents are not flexible in communicating non-verbally and fail to respond at each age level with appropriate motions. An impoverishment of communication and character development can be observed in those children, who grow up in surroundings, where the verbal was emphasized too early and when messages expressed in non-verbal terms were left unanswered.

Ruesch and Kees here are referring to the development of the hearing child. How much greater impoverishment of communication and character development may we anticipate in the deaf child, where the non-verbal constitutes his only method of communicating.

EFFECTS OF ENFORCED RESTRICTION OF COMMUNICATION AMONG PEERS

One of the important phases in the development of the individual is the period during which he begins to shift from a total dependency on the family to a widening relationship with his peers. For the deaf child this again presents special problems. Up to the age when speech becomes significant as a means of communication, the deaf child experiences no problem that we can perceive, in relation with other children, since communication is on a non-verbal and action level. However, with the acquisition of speech by the hearing child, difficulties begin. The hearing child begins to wonder why his playmate does not respond when he talks and also why he can not understand the sounds made by the deaf child. The deaf child begins to sense a change in his relationship with his friend. He finds that his hearing friend understands less and less what he tries to convey and likewise begins to find that he understands less and less what the hearing child tries to convey to him. As time goes on, the deaf child begins to give up the attempt to communicate, except on a very concrete level. And unless the environment is very patient and understanding, which it rarely is, the deaf child withdraws more and more. Where the deaf child is getting oral speech, in the early years, this is only a slight help, because it is many years before the speech of the deaf child becomes intelligible in any way comparable to that of the hearing child. Even where there are interested adults around to help the deaf child, the difficulty in communication still prejudices a truly meaningful interpersonal relationship.

Case 1 : S. is a little girl of 7½ who, since the age of 3, has been going to a school for the deaf. S. apparently has a congenital hearing defect with a loss of approximately 80 decibels in both ears. At her school only oral speech is allowed. The children never are permitted to use gestures or the sign language, are punished for signing, and praised for using only oral speech.

At the age of 5, S. was sent during the summer to day camp. There she was the only child who had no intelligible speech, except for a few isolated words and phrases. Her school

had requested a report from the camp in regard to her experience there, and at the end of the summer the camp wrote a glowing report describing how bright she was, how well she adapted to all the camp routines, activities, etc. However, one statement that they did make suggests what I was trying to say earlier. It was this: "No child in camp selected S. as a companion."

It is an instructive experience to observe a deaf child attempting to be included as a part of a group of hearing children, and to note the transformation that occurs in the child at the approach of another deaf child. It is as if the child suddenly comes to life. The eyes and face light up. There is a change from a human being who is fairly quiet and somewhat perplexed to a vibrant communicating alive personality. Suddenly there is so much to say with gestures, signs, face and body, and one senses that the child now feels that he will be understood and responded to in an understandable manner. One senses in watching this scene that with the advent of another person with whom the child can communicate life takes on a different meaning.

The need for human beings to communicate is one of the most basic needs. In the deaf child the pace at which he acquires oral speech or the ability to talk is far too slow to meet this need. One has only to observe what happens when school is over and the children are away from the watchful eyes of the school authorities. Then as if a dam has burst, they begin to talk. They "talk" and they may even be accompanying verbalization of words here and there. But what one mainly observes is the communication that goes on through signing. Then they are really talking, and then one gets the sense that a meaningful emotional exchange is taking place between and among them.

If a deaf child is continually exposed to other deaf people who communicate by signing, there will be no need for formal instruction in the sign language. The child will learn of his own accord something that he senses is so vital and important to him. Parent R. reported this experience with her child. B. was a pupil at a school where signing was not allowed and the

school prided itself on this fact. There was never discussion between the child and parent about signing. However, one time when B. was about 5 years of age, the parent went into the bedroom where the child slept to get something. The child was lying in bed facing away from the doorway. As the parent walked into the room, she observed the child lying in bed practicing signs and the alphabet. As soon as the child saw the parent he stopped.

The question then that is raised is the following: What is the effect on the growing child in terms of his relationship with peers, where the feeling is fostered that one of the most vital facets of the relationship is one that is bad, and must be hidden at all times?

The growing child needs the relationship of peers to help establish an aspect of its identity. Healthy peer relationship helps the child separate itself in a healthy way from the very dependent family relationship it has been subjected to from birth. However, how is the child's image of the relationship distorted when the very basis on which it exists, namely, the ability to communicate with another, becomes laden with guilt. A healthy peer relationship becomes integrated into a healthy family relationship. And *vice versa*, a healthy family relationship helps the child develop healthy peer relationships. Can such a reciprocal healthy process occur where the child is made to feel that one of the most basic aspects of the relationship is unacceptable? It becomes a matter of friends versus family and to the child's burden of establishing his own identity is added the burden of the split that occurs between the child as part of the family and the child as part of a peer group. The child then does not experience growth as a continuum along a general line of development, but rather finds itself in the position of suddenly being in conflict concerning the very process of growth itself. Because growth to a very great extent is dependent on the ability of the growing organism to communicate meaningfully with its environment, growth and communication go hand in hand. And since in the deaf child such severe conflicts and restrictions are placed on communication, this must have the ef-

fect of producing severe conflict and restriction on the deaf child's ability to grow.

Finally, I wish briefly to question the effect of such restriction on the deaf child's intellectual development. We do know that intellectual development is to a considerable extent related to the development of language. To quote Dollard and Muller(3) :

Reasoning is essentially a process of substituting internal, cue-producing responses for overt acts. As such it is vastly more efficient than overt trial and error. Not only does it serve the function of testing symbolically the various alternatives, it also makes possible the substitution of anticipatory responses, which may be more effective than any of the overt response alternatives originally available.

It is language that supplies the symbols. But for the deaf child the process of learning these oral symbols is a long and slow one.

Dr. Edna S. Levine(4) says :

Even at best the task of verbalizing minds-without-words, whatever the means, is a slow exhaustive process. The pupil's needs for life enlightenment begin to outstrip the store of language he is so painstakingly learning. The problem is how to get such information across to him when he has not yet mastered enough language for understanding explanations.

It is here that I feel that the use of signs helps the deaf child make up this deficit to some extent. These are symbols for the child to use until such time as he acquires the oral symbols that may then replace or

reinforce the manual symbols. But at least until such time as he acquires adequate oral symbols, he is not denied the use of any that are meaningful to him and that enable him to test symbolically various alternatives, rather than continually function in a trial and error acting response.

SUMMARY

This paper does not criticize the great work that is being done to promote the meaningful growth and education of the deaf child and helping him to achieve as much oral facility as possible. It is presented in the hope that hand in hand with this, there will be a more tolerant attitude to the deaf child's need for language through signs, until such time as language through oral speech may replace it. It is felt that one may enhance the other, rather than being antithetical to each other. Some of the negative aspects of the present attitude have been presented with the hope that the questions raised here will arouse further interest in this matter and stimulate others to study this problem.

MURDERING MOTHERS¹

WERNER TUTEUR, M.D., AND JACOB GLOTZER, M.A.²

Medea, the outstanding example of multiple filicide in Greek mythology, murdered her children after she had been abandoned by Jason, her husband, for another woman. It is of interest, however, that she also had serious difficulties in her relationship to her own father and had also assisted Jason in the murder of her brother previously.

In 1937 Lauretta Bender(1) postulated that child murders by parents are suicidal acts as a result of identification with the child, not primarily an act of hatred against the child. The attempt may start as a suicidal drive, gradually converting to an attempt to kill both self and child, but ending in just killing the child. Likewise, it may be an effort to escape the turmoils of life, real or delusional, and the child victim becomes part of the escaping personality. Wertham(2) amplifies on cathartic behavior, a concept first introduced by Hans W. Mayer in 1912. It is usually accompanied by marked egocentric behavior and a disturbed balance between logic and affectivity. Helene Deutsch(3) states that women who have not received maternal love in their childhood develop less motherliness than others. Often their own rejection of the mother inhibits their maternal feelings. The well integrated mother expands her ego through her child, the maladjusted feels restricted and impoverished through him. Unbearable pressure of reality in the conflict between self preservation and motherhood may lead to complete rejection. McDermaid(4) stresses a conscious feeling of inability to bring up the child which may lead to filicide. Socio-economic factors, likewise mentioned by McDermaid, may readily enter motivation toward the deed. Melanie Klein(5) states that the rejected child may grow up to be cruel. Bromberg(6) mentions that the victim often represents the murderer in the

latter's unconscious. Pollak(7) finds that the type particularly exposed to female homicide are children and persons to whom women are related or in close contact. It seems to him that filicide and the abandonment of children are specifically female deeds. Podolsky(8) speaks of the unpredictability of filicide, that the background of the parent is usually of a complex nature and that the deed as such indicates a short circuit reaction.

While obviously there remains considerable controversy regarding the motivation toward filicide, the following 5 cases admitted to Elgin State Hospital during 1956 to 1958, may serve as further illustrations to behavior widely publicized when it occurs, but little understood.

Case 1.—(L.D.) White female. Born in 1928, in Central Illinois. Age at filicide, 27. Admitted 10-23-58. Discharged by writ of habeas corpus on 4-5-57. She is of French-Irish-Jewish descent, has no religious affiliations, separated from her husband. Began to support herself as a strip-teaser after 3 years of high school. On February 26, 1955, patient killed her daughter, aged 3, her only child, by giving her an overdose of seconal and nembutal mixed in tomato juice in a hotel room. Following this she took a sizable amount of the same capsules herself, in a serious suicidal attempt. The patient is of illegitimate birth, and while her mother was married 4 times, she had never married the patient's natural father. Also, the mother bore no children from her 4 marriages. The patient, however, grew up in dire emotional, physical and material neglect, at one time during her adolescence even being approached sexually by one of her 4 stepfathers. This chaotic background was further colored by frequent institutionalizations in homes for neglected children and by equally frequent and disturbing changes of school. Finally, at age 17, the mother describes her as "impudent, disobedient and defiant," whereas the patient in turn accuses her mother of exploiting her as soon as she became gainfully employed. She first worked as a waitress, then entered show business. At age 20 she entered a common-law marriage relationship with a highly inadequate male

¹ Read at the 115th annual meeting of The American Psychiatric Association, Philadelphia, Pa., Apr. 27-May 1, 1959.

² Clinical Director and Senior Psychologist, Elgin State Hospital, Elgin, Ill.

who acted as her procurer for pleasure seeking men, being thus supported by her. This relationship nevertheless resulted in legal marriage after 3 years. Since the age of 21 she had been habituated to barbiturates and possibly marijuana. When she was 23, she gave birth to the daughter victim. Both pregnancy and delivery had been difficult. The couple separated soon after the birth of the child, and while her mother tried in vain to assist her by taking care of the baby, the patient preferred to live by herself and follow her career in show business. This resulted in the mother at times being thrown out of patient's home and the baby being sadly neglected. Early in 1955 the patient contracted pneumonia. During this illness and after recovery, she found herself in such destitute financial circumstances that welfare agencies tried to place the child away from her. In utter desperation the murder-suicide attempt took place in a racially mixed Chicago South Side hotel. Mother and child were discovered after 40 hours by a house detective, the mother in deep coma. Significantly, she had left this suicide note: "Bury us together in one box, please. We belong together, you know." Regarding her survival, she stated that "God did not want her to die and that she had to comply with his wish." Arrested and placed in jail for murdering her child, a jury found her insane at a sanity hearing. Then followed hospitalization at Kankakee State Hospital, which resulted in another sanity hearing in 1956, finding her "not recovered." She arrived at Elgin State Hospital as a transfer. While with us she maintained the delusion that during her illness her 3-year-old-child nursed her and took care of her "financial affairs." At various times the patient was found to be a behavior problem, but as a whole she presented a picture of an extremely immature and adolescent person.

Case 2.—(C.B.) White female. Born in 1922, in Northern Illinois. Age at filicide, 35. Admitted 4-7-57. She is of Scotch-Irish descent and protestant religion, married, attending to household duties, and graduated from high school at age 17. One day prior to admission she choked to death with her hands her 11 year old daughter while at home. Patient's father is described as having been too strict and demanding of his children, while the mother was excitable and emotionally unstable. Patient is third of 4 siblings, with whom there was strong rivalry. She stated that her parents failed to satisfy her need for affection during the formative years. Her oldest sister was committed to a mental hospital in

1939. This sister's daughter has been an epileptic since age 12. There was a paternal aunt who had a "nervous breakdown" in 1920. Patient married in 1941, when she was 19 years of age. There were 3 children from this union: a daughter, born in 1946 (the victim), and 2 sons born in 1948 and 1953. Four years after marriage she developed a "nervous stomach and undefined headaches," and felt deserted when her husband left her to serve with the Armed Forces during World War II. There were 3 major disturbing situations in the patient's life prior to commitment of the deed: 1. Her husband had openly rejected her, 2. A younger sister became subject to serious marital difficulties, and 3. The older son, then aged 9, was diagnosed as suffering from a severe heart defect. As a reaction to this, patient turned intensively to religion. On the night of the victim's 11th birthday, patient choked her to death, allegedly obeying a divine command. A few days after admission she tried to strangle herself with the wire of a mattress. Retrospectively, she described the child victim as a discipline problem. Patient was discharged on 10-16-57 as having recovered from a schizophrenic episode during which the tragedy took place, and is presently reported by the family as doing well. Immediately after her arrest she was taken to a sanitarium, and the following day was transferred to us.

Case 3—(V.D.) White female. Born in 1910, in Vermont, Illinois. Age at filicide, 47. Admitted 2-25-58. She is a widow, of Irish-Dutch descent and protestant religion. Graduated from high school at age 18. She worked at many trades, but has been employed as a factory worker prior to commitment. On 8-28-57 patient shot to death her feeble-minded son, 14 years of age, while visiting him at a mental institution. Patient stated that her father died of the flu when she was 8; she remembers him as friendly. Following father's death her mother was forced to resume her profession as a registered nurse. Her mother died when patient was 26. She is second of 3 siblings, who got along well but were left to shift for themselves when mother was away from home, with minimal supervision by the grandmother. After graduating from high school she started working as a photographer's helper. She met her husband, 11 years her senior, at a photographer's meeting, and the two eloped and were married in 1936. She describes the husband as quick tempered and "hard to get along with." They were divorced after 3 years, but significantly, after the divorce she continued to live in the back room

of his studio. Three years later they remarried. There were 3 boys born to this eccentric union: one during the first marriage, the second during the divorce period, and the third (the victim) who had been conceived during the divorce period but born after the husband's death, which happened shortly after the remarriage. The two older children had been placed with welfare agencies during the divorce period, but after the husband's death all 3 were placed until 1952, when the patient demanded them back and tried to support them with her meager wages as a factory worker. The 3 children lived in perpetual strife after their return to the mother and the oldest openly expressed his hostility towards the youngest, the feeble-minded. Finally the authorities placed the latter in a public mental institution. There, during a visit, she shot him while taking him into her arms, and was immediately arrested. Already in 1942 she was described as secretive and suspicious, but prior to committing the deed she had been overheard saying that she would rather see her children die than suffer. Brought to trial on 12-9-57, she was acquitted and started to keep house with her second son. Only when she told a welfare worker she might have to kill him also unless she received public assistance, was she committed. She blames the tragedy on financial embarrassment and says that she couldn't see the child stay in an institution. Presently her frame of reference and her concept of reality remain that of a schizophrenic, and psychological testing confirmed this.

Case 4.—(B.F.) White female. Born in 1930, in Bonaparte, Iowa. Age at filicide, 27. Admitted 4-25-58. She is a protestant, married housewife, who used to be active as a trade newspaper editor and has a 4 year college education, majoring in journalism. On February 6, 1957, she drowned her 3 children in a water filled bathtub at home. They were a boy, aged 5, and twin girls, aged 3. Patient then attempted suicide by first trying to drown herself in the same bathtub. Failing, she attempted to electrocute herself at the fuse box, then drank ammonia, causing burns in mouth and throat. As a last desperate attempt she turned on the gas stove, placing her head in it. In this position she was found by her husband, unconscious, but later revived. Her father, who was a veterinarian, played a very minor part in the family, being completely absorbed in his profession. Patient was closer to the mother, but even from her she received very little affection, as did the other siblings. There were 4 sisters, among whom the patient

ranked third. She remembers her mother frequently expressing a deprecatory attitude towards all males and regretting ever having married. Much criticism, but little praise colored the parents' attitude toward the children. She graduated from high school at age 16, and was valedictorian of her class. She then went to the University of Iowa and graduated with a degree in journalism, to become editor of a small business magazine. During her scholastic years she applied herself fully to her academic studies, neglecting her social life. She married at age 21, in 1951. Her husband is described as a very domineering person, who subjected his wife to perennial criticism and gave the patient a constant feeling of insecurity. The boy was born one year after marriage, the twin girls about two years later. After marriage the patient gave up journalism and the husband supported the family by managing a dress shop in a Chicago suburb. He is said to have been more concerned with his business and the physical aspect of the home than with his family as individuals. Already in 1956 the patient expressed feelings of hopelessness, despair and despondency. She felt "like dying," she became overprotective of her children and began to resent the husband severely. The son had recently developed a serious eye disease. On 1-2-57 when their house caught fire, she saved the boy, the husband saved the twins. After this she began to feel that the children were suffering as much as she was and a need developed in her to do away with "all of us," this statement apparently excluding the husband. This culminated on February 6 of the same year in the tragic event. After regaining consciousness she made statements to the effect that "she had to do it, that it was too much for her and that God could do more for the children." Also, that she felt she "had nothing to live for, and experienced a general feeling of confusion and a need to get rid of the children." After her arrest she was given a sanity hearing and found insane. Committed to another mental institution, she tried unsuccessfully to obtain a discharge on a writ of habeas corpus on 1-13-58, and was transferred to Elgin State Hospital. At the previous mental institution she was observed to be overtly depressed. From this overt depression she recovered, but while under our observation it became evident that she harbored great resentment towards mother and siblings during her developmental years.

Case 5.—(S.E.) White female. Born in 1921, in Montclair, N. J. Of Italian extraction and of Catholic faith. She remains married, and had

been working as a secretary during the period marking the tragic event. She graduated from high school at 17 years of age. Age at filicide, 37. Admitted 8-27-58. On 8-22-58, while at home, she fatally shot in the back her two children, a boy, aged 6, and a girl, aged 3½, then tried to commit suicide immediately after by taking an overdose of tranquilizers. Her father stated that he never had a close relationship to his children, whereas mother and patient are described as close. The patient has one sister 2 years younger than herself. While her childhood and developmental years are described by her as being reasonably happy, this did not hold true for her two marriages. Her first marriage took place at age 19, and ended in divorce on grounds of cruelty after 4 years. Her first husband is described by her as high strung and difficult to understand. There were no children. Following the divorce the patient served one year as a WAVE. Her second marriage took place at age 27, in 1948. The first child was born 3 years later, and the second, 6 years after marriage. Shortly after the birth of the second child the husband left her for another woman, returning soon afterward in remorse. The patient had been hospitalized for psychiatric reasons in 1955, after she had learned of her husband's affair and also following a skull fracture the boy had suffered in an accident. While hospitalized she received EST. In 1957 the family moved to the Chicago area. Here she worked as a secretary to a manager of a theater. On the day before the tragedy the patient frantically called her husband, who was in the East, to return home immediately, but he arrived too late. Her stated motivation following the deed was that she killed the children because she feared being returned to a mental institution. Other statements elicited from patient since were as follows: "My brain was awake 24 hours that day. Could it be that I am dreaming? It was horrible. I was sick. We had financial trouble and I had to go to work. My husband traveled a lot on business. I lost my mind. It seemed that everything went wrong. I thought my children would have peace of mind in death. Everything piled up on me. I thought I would end it all. I had no place to leave the children. I was confused." The day following her arrest she was taken to Elgin State Hospital.

SODIUM AMYTAL INTERVIEWS

Cases 3, 4 and 5 are presently in the institution, and on January 4, 1959, sodium amytal interviews were performed on them. Case 3 exhibited florid manifestations of

her psychosis under narcosis, strongly emphasizing that she felt fully justified in what she had done, that "feeble-minded children must be done away with, if necessary, even by physicians," but that she may not repeat her act. In Case 4, the interview resulted in profuse crying when the tragic event was brought up, a reaction that remained absent when she was awake. Her overall feelings of inadequacy and inability to raise children, combined with a wish to "save them," concomitant with her suicide, was the tenor of her statements. "I had failed at everything else, so that I at least wanted to succeed with this" she said. Case 5 reiterated her feelings of rejection by her husband. "When my husband left, I was shocked, I got on my knees and asked God that my husband should come back. The trouble started when he came back—I would not trust him."

DISCUSSION

Case 3 still remains overtly schizophrenic. She is the only one who did *not* plan suicide. It is our impression that she is unable to accept imperfection regarding herself as well as in the 14 year old victim. She cannot allow that a part of her—her child—is organically defective. The confinement of her son at a mental institution was publicly exhibited evidence that pointed to her defectiveness, which was finally resolved by her act. She does not and cannot see that she has done wrong to anyone and feels justified in having done what she did. Her having been acquitted supports her feelings of justification—society has thus, in her mind, approved her deed.

All 5 cases show similarities: the 5 mothers experienced a definite coolness either from one or both parents during their childhood years, when the concept of motherliness begins to develop in the female. Without exception, all mothers had difficulties with their spouses, ranging from rejection, unfaithfulness and separation to divorce. With one exception, (Case 3), the entire group clearly involves filicide-suicide.

Suicide-murder may be interpreted as an attempt to remove the "total-all," the actual and the *extended-self*, so that nothing of the "self" remains. All 5 mothers revealed a feeling of extreme inadequacy and of in-

ability to raise children. In all of the suicidal ones a deep feeling of rejection by at least one important figure was present, creating a feeling of insecurity and non-acceptance of self to such a degree that life became unbearable and the "total-all" had to be removed. In Cases 2, 4 and 5 the mothers were aware of a physical deficiency of their children. This might have contributed to their own feeling of worthlessness and to the suicidal intent. Cases 4 and 5 are willing to explain their acts as breaks of insanity, as they cannot otherwise reasonably explain them. Case 2 maintains that she had divine direction, thus also claiming extraordinary circumstances, while Case 3 declares full justification for her act in the interest of the child, who was retarded and in a state hospital. Case 1 was overwhelmed by external circumstances when committing the deed and was not equipped to face them. In all cases the mothers are in effect attempting to explain their act by some extraordinary circumstance or condition which would suggest that they at least see intellectually the enormity and wrongness of their deeds.

History and psychiatric and psychological material of all 5 cases point to the diagnosis of schizophrenia, probably acute state at time of act. The balance between logic and affectivity was clearly faulty in each case, at least during the deed, and it was particularly this disparity which then indicated schizophrenic thinking. Cases 2, 4 and 5 would appear to be in fair remission, but Case 3 (the one justifying her deed) still strongly manifests highly unrealistic ideation. The whereabouts of Case 1 remains unknown. There is still evidence of much anxiety, apprehension, and a great deal of underlying conflict that has not been resolved, at least in Cases 3, 4 and 5. Socio-economic pressure entered in only 2 cases (1 and 3).

Interestingly enough, the prominent features which *did* vary in the series was the mode of killing: 2 mothers used shooting, the other 3 strangulation, poisoning and drowning.

All mothers appear regretful of the act, declaring that they would never commit it again on another child.

While there is similarity in background

pattern, one cannot possibly place all or any motivation towards filicide above one common denominator. Every factor mentioned initially in the review of the literature could be traced, but there will always remain individual variations as to nature and combinations of these factors and there are in all probability other unknown factors involved in such abnormal behavior.

Mundy-Castle(9) reports that murderers who are declared insane, or whose crimes are unmotivated, show an unusually high incidence of abnormality in the EEG. Cases 3, 4 and 5 had EEGs which showed repeatedly isolated diphasic spike activity in the temporal areas suggestive of psychomotor equivalent states. (W. C. Wilson, M.D., electroencephalographer, Glen Ellyn, Ill.) Obviously further investigation is needed in this area.

SUMMARY

Five cases of filicide committed by mothers are reported. Filicide remains an abnormality, primarily restricted to the female. Faulty relationships to either parent or extremely poor marital adjustment, or both, were present in each case. Four cases were combined with serious suicidal attempts, and a feeling of general inadequacy and inability to raise children was admitted by all mothers. All 5 appeared regretful of the act and state that they would never repeat it. The disparity between logic and affectivity was so strong in each case during commitment of the act that a diagnosis of schizophrenic break was justified in all 5. Motivations of punishment, revenge and secondary gain, as usually seen in ordinary murders were, to all appearances, completely absent. The primarily conceived suicidal attempts of the mothers rule these out almost logically. Thus, the suicidal attempts in no way represent an escape from the legal consequence of having done away with human life. A general feeling of unacceptance led to the suicide, and the "total-all"—including anything that belonged to the mother—had to abandon earthly existence, hence the combined filicide-suicide. Two cases involved 2 and 3 victims, respectively, the remainder one each. The mode of killing differed: two cases of shooting, one each of choking, poisoning and drowning. Ages of mothers

anged from 27 years to 47 years, of victims from 3 to 14 years.

CLINICAL NOTES

THE EFFECT OF RO-5-0831/1 (MARPLAN) IN DEPRESSIVE STATES

H. AZIMA, M.D., H. DUROST, M.D., DOROTHY ARTHURS, R.N.,
AND A. SILVER, M.D.¹

Since the discovery of substances loosely called inhibitors or tranquilizers, the search for excitator drugs or anti-depressants was inevitable. The discovery of anti-depressant action of iproniazid led to the exploration of a series of its less toxic and more effective analogues. It was assumed that the amino-oxidase inhibitory action of iproniazid was responsible for its anti-depressant activity. Even though this idea has proven to be untenable, several substances developed in this manner seemed to be effective against depression. Of these RO-5-0831/1² was the most promising. This substance is 1-Benzyl-2-(5-methyl-3-isoxazolylicarbonyl)hydrazine. In laboratory experiments it is considerably more potent than iproniazid in its amino-oxidase inhibition, 5-hydroxytryptophane potentiation and reserpine blocking activity.

A preliminary trial of RO-5-0831/1 was undertaken in 65 patients: 32 neurotic, 22 psychotic depressions, and 11 other syndromes (9 schizoaffective psychoses and 2 anxiety neuroses). There were 40 females and 25 males, average age 50 (the oldest 81 the youngest 15). The drug was administered orally with an average daily dose of 75 mg. (minimum 60 mg. and maximum 800 mg.), for an average period of 3 weeks (longest 3 months, shortest 5 days), with a 6 months followup. To increase the reliability of the assessment of the drug effect, two methods of evaluation were used: 1. Multiple observers, i.e. 8 psychiatrists (4 psychoanalytically oriented and 4 eclectic), and one research nurse assessed the therapeutic response; 2. Double blind studies without the use of placebo. This consisted of the establishment of a ward where all staff members are ignorant of the nature of

the different drugs used. In the present study 51 patients were assessed with the first and 14 with the second method. The criterion of improvement was the degree of symptomatic relief, based upon the following: behavioral (retardation, sleep and appetite) and experiential (guilt feelings, sadness, hopelessness). Relief under these 6 items was rated as marked, moderate and nil, and the final assessment was based upon the combination of the ratings. Laboratory tests consisted of weekly white and red blood count, transaminase, alkaline phosphatase, urine analysis; and twice daily blood pressure and TPR were performed with the first 40 patients.

The results of the two methods of assessment paralleled each other.

Among the 32 neurotic depressions, 5 showed marked and 12 moderate improvement; among 22 psychotic depressions, 7 marked and 10 moderate improvement. Thus the percentage of significantly improved patients was 60.3%, (22.2% marked and 38.1% moderate). Among the 11 basically non-depressed patients only 2 showed moderate improvement and that in the depressive component of their schizoaffective states.

It should be noted that the psychotic, so-called endogenous, depressions responded more fully to the drug and all of the improved patients in this category and some of those in the neurotic depressed category would have received electric shock, if they had not received Marplan. There was a therapeutic lag from 3 to 10 days in 70% of the patients, and it appeared that the optimum followup duration of Marplan therapy should be about one month after the relief of symptoms.

Side effects consisted of frontal headache, 17 patients, dizziness and fatigue, 12, tremor, 9, hypotensive attacks associated with fainting spells and falling, 3, oedema of ankle, 2, metrorrhagia and epistaxis, 1.

¹From McGill University and Allan Memorial Institute, Montreal and Verdun Protestant Hospital, Montreal, Can.

²RO-5-0831/1 supplied by Hoffman Laroche Limited.

The latter could not actually be attributed to the drug. Laboratory test findings remained within normal limits in all 40 patients tested.

CONCLUSIONS

1. RO-5-0831/1 is a sufficiently potent

anti-depressant to require further study. 2. It should be tried in instances where other anti-depressants have failed; 3. It brings into the therapeutic arsenal of depression the possibility of choice according to the patient responsivity.

CLINICAL EVALUATION OF CYCLOHEXALAMINE

PAUL E. FELDMAN, M.D.¹

A series of 55, chronically psychotic, hospitalized patients were treated with cyclohexalamine (Parke Davis Compound C-401) for an average of 78 days. The test group consisted of 49 schizophrenic patients, 3 manic-manics and 3 organic brain syndrome patients.

Maximum daily dosages varied from 20-80 mg. with the majority of the patients receiving 20 mg./day. Careful and frequent laboratory checks on renal, hepatic and hemopoetic functions were maintained throughout the treatment period.

At the termination of the study, 4 patients were found to have developed parkinsonism and one had developed urinary retention which subsided when treatment was stopped. The cases of parkinsonism were very adequately controlled by anti-parkinsonism drugs. No other side effects or untoward developments were noted. Significantly, this compound did not appear to cause drowsiness.

The laboratory reports were characterized by sporadic and unpredictable abnormal readings, completely unrelated to any clinical findings. This phenomenon has been noted in the past with other non-toxic compounds.

One-third of the patients responded with significant clinical improvement (moderate or marked overall improvement). The primary responses which accounted for this improvement were those usually seen with phenothiazine therapy, i.e., amelioration of delusions, hallucinations, negativism, hyperactivity, hostility and combativeness. In view of the chronicity of the patients' illnesses and their poor prognoses, this is considered to be a modest accomplishment.

The results in general warrant the recommendation that cyclohexalamine be subjected to further testing and evaluation, preferably upon a group of prognostically favorable patients.

(Laboratory data and responses of specific areas of behavior to cyclohexalamine are available upon request from the author.)

ON THE RELATIONSHIP OF ADRENALINE AND ITS OXIDATION PRODUCTS TO SCHIZOPHRENIA

AARON FELDSTEIN¹

In 1952, Osmond and Smythies(1) put forth the interesting hypothesis that an abnormal metabolite of adrenaline was causally related to schizophrenia. Harley-Mason (2) suggested a methylated derivative of adrenaline, and Hoffer, Osmond, and

Smythies(3) suggested adrenochrome and adrenolutin. Hoagland, Rinkel and Hyde (4) thought that "adrenoxine" might be the toxic factor.

Hoffer has offered evidence in support of the hypothesis that adrenochrome is causally related to schizophrenia, evidence relating to the presence of adrenochrome

¹ Worcester Foundation for Experimental Biology, Shrewsbury, Mass.

in blood and the ability of adrenochrome to cause mental disturbances in man. It was reported(5) that when erythrocytes from schizophrenic patients were extracted with acetone a substance was obtained with an activation peak at $475 m\mu$ and a fluorescence peak at $480 m\mu$ which was stated to be characteristic of adrenochrome. However, adrenochrome in acetone does not fluoresce(6). The maxima observed were probably due to scatter light. The conclusion that adrenochrome is present in the erythrocytes of schizophrenic patients is therefore not justified by the evidence.

Hoffer, Payza and coworkers also have cited evidence for the presence of adrenochrome in the plasma of normal subjects(6, 7, 8, 9) and of schizophrenic patients(9). The evidence for the existence of adrenochrome in plasma is based upon an analyti-

cal method developed by Payza(6).²

A modification of the original method for the fluorimetric analysis has recently been published(6). Blood (heparinized) is drawn and centrifuged. To 1 cc. of plasma there are added 2 cc. of a zinc acetate ascorbic acid solution. After 30 seconds, 4 cc. of an acetone-ascorbic acid solution are added. Five minutes later, the reaction mixture is filtered and the filtrate read in a spectrophotofluorimeter at λ 400 $m\mu$, λ 500 $m\mu$. The method includes a blank and a recovery experiment.

Our investigations have led us to believe that the fluorimetric procedure does not

² We are grateful to Dr. Payza and Dr. Hoffer for extending an invitation to visit their laboratory and learn the methodology first hand; we are grateful also for data supplied in advance of publication and for a generous sample of pure adrenochrome.

FIGURE 1

Curve 1 (X X): The activation spectrum of the reaction product of pure adrenochrome with zinc acetate and ascorbic acid added to a sample of plasma obtained from a normal subject. The spectrum was obtained ten minutes after the addition of the reagents. Curve 2 (O O): The activation spectrum of the reaction product of zinc acetate and ascorbic acid added to a sample of the same plasma. The spectrum was obtained ten minutes after addition of the reagents. In order to reproduce the activation spectra accurately it is necessary to time the reaction period from the moment zinc acetate comes into contact with ascorbic acid. If the plasma reaction mixture is allowed to stand an excessive amount of time, the 340 and 420 $m\mu$ peaks as shown in curve 1 will disappear and be replaced by the 390 $m\mu$ peak due to the reaction of zinc acetate with ascorbic acid. This might easily be interpreted incorrectly.

measure adrenochrome endogenously found in plasma, but that the procedure measures instead an artifact due to the reaction of zinc acetate and ascorbic acid. Our evidence is based upon a study of activation maxima which were not investigated in the published procedure(6).

In the absence of plasma, zinc acetate and ascorbic acid in acetone reacted to give a fluorescent substance with an activation peak at 390 $m\mu$ and a fluorescence peak at 500 $m\mu$; in the presence of plasma, the peaks were also found at λ 390 $m\mu$, F 500 $m\mu$. In the absence of plasma, added adrenochrome reacted with zinc acetate to give a fluorescent substance with two peaks, a major one at λ 420 $m\mu$, F 505 $m\mu$ and a minor one at λ 340 $m\mu$, F 505 $m\mu$; similarly, in the presence of plasma, added adrenochrome reacted to give a fluorescent substance with a peak at λ 420 $m\mu$, F 505 $m\mu$ and a minor one at λ 340 $m\mu$, F 505 $m\mu$. Fig. 1 shows the activation spectra in plasma after the addition of zinc acetate and ascorbic acid, in the absence of adrenochrome (Fig. 1, curve 2) and in the presence of adrenochrome (Fig. 1, curve 1). The details of this work will be published elsewhere(10).

We have never been able to find the 350 $m\mu$ or the 420 $m\mu$ activation maxima, characteristic of the adrenochrome-zinc acetate reaction product, in any of the plasma samples we obtained from normal subjects or schizophrenic patients. On the other hand, we have always observed the 390 $m\mu$ activation maximum, characteristic of the

zinc acetate-ascorbic acid reaction product, in the same plasma samples. Our conclusion is, therefore, that the presence of adrenochrome in plasma of normal subjects and schizophrenic patients has not been proved. It is important to note that Szara, Axelrod and Perlin(11) have reported that they could not detect endogenous adrenochrome in plasma.

A NOTE ON THE CLINICAL EFFECTS OF PERPHENAZINE AT VERY HIGH DOSAGES

ARTHUR N. LARSON, M.D.,¹ JOHN S. HAMLON, M.D.,¹ AND
LLOYD K. SINES, Ph.D.²

The clinical effects of perphenazine (Trilafon) at very high dosages were studied in a small sample³ of chronic, semi-regressed female psychiatric patients. An initial dosage of 8 mgm. t.i.d. was commenced on all

cases, and was increased rapidly in order to reach a maximum dosage within the first 2 or 3 weeks of the study. Maximum dosage was determined for each patient indi-

¹ Fergus Falls State Hospital, Minn.

² Director of Research, Fergus Falls State Hospital, Minn. Now Research Associate, University of Minnesota.

³ Ten patients were selected. Age range : 36-63 years (average 54.2) ; length of hospitalization : 3-37 years (average 19.1 years). Six were schizophrenics, 2 were mental defectives, one a chronic brain syndrome with psychosis, and one a paranoid state.

vidually on the basis of the appearance of untoward physical reactions, or specific signs of toxicity. Medication was then decreased to a maintenance dosage, i.e., the point at which the maximum therapeutic effect and minimum untoward side effects were obtained. Maximum dosages ranged from 384 to 768 mgm. per day, with an average of 565 mgm. per day. The number of days from the beginning of the drug period to the attainment of maximum dosage ranged from 18 to 29. Maximum dosages were maintained for 1 to 13 days. Maintenance dosages ranged from 12 to 144 mgm. per day (average of 76 mgm. per day), and were continued for 6 to 47 days (average 30 days).

A brief physical examination, gross psychiatric screening, and blood pressure determinations were performed by the ward physician on an average of 3 times a week. Periodic white blood count and differential count were also obtained.

The patients' responses to high dosages of Trilafon were quite variable. In terms of therapeutic response, 4 patients were judged by the physician to have improved by the end of the drug regime, while 2 were judged to have become worse. One of the 4 improved showed a *marked* therapeutic response at a dosage of 576 mgm. per day, but then rapidly deteriorated into a catatonic-like state with accompanying severe extrapyramidal symptomatology. The generalized "shock-syndrome" noted by Weiss, *et al.*, was also observed in one instance.

Several significant physiological effects of the drug were noted, including: 1. A consistent and marked hypotensive effect, (observed with all patients) which persisted even after a 6-week period following withdrawal of the drug. This finding is at

variance with those of other investigators using Trilafon at conventional dosages. 2. Extra-pyramidal signs including tremor, rigidity, and/or drooling in 1/3 of the cases, and 3. A marked soporific effect at the highest dosages among 8 of the patients. Miscellaneous side effects including ankle edema, facial pallor, slurred speech, and constipation were observed in two or more instances. In addition, each of the following was observed in at least one of the 10 patients studied: gait disturbance, tachycardia, reduced appetite, gastric distress, urinary urgency with incontinence, and (possibly) an exacerbation of a previously existing seizure syndrome. Finally, a consistent diminution in activity level was observed among 9 of the 10 patients studied, as was a general decrease in verbal output. Blood dyscrasias, visual or other sensory impairments, hyperthermia, extreme variations in weight, and other severe debilitating effects were not observed.

It would appear that the clinical effects of perphenazine at extremely high dosage levels are essentially the same as those observed within the usual lower dosage range. Side effects were observed in approximately the same proportion of cases as has been reported for conventional dosages and, with the exception of a consistent hypotensive effect, no new or unusually complicating reactions were observed in the unusually high ranges employed in the present study. Even the "shock-syndrome" observed in the present series has been reported with the conventional dosage range. It would appear, therefore, that perphenazine has rather broad limits of therapeutic safety, though it seems likely (from this and other studies) that its therapeutic effectiveness may be obtained at relatively low dosage levels.

CLINICAL EVALUATION OF A NEW PHENOTHIAZINE TRANQUILIZER, FLUPHENAZINE (PROLIXIN)

IRVING J. TAYLOR, M.D.,¹

Over the past year, fluphenazine, identified as Prolixin², a trifluoromethyl derivative of hydroxyethyl piperazine propyl

phenothiazine, has been administered to 188 patients with mental illnesses who reported to this hospital for treatment. In these trials, fluphenazine proved to be the most potent of all the phenothiazines used,

¹ Taylor Manor Hospital, Ellicott City, Md.

² Supplied by E. R. Squibb & Sons.

as others have shown(1). Fluphenazine possesses marked tranquilizing activity with strong anti-hallucinatory and anti-delusional properties and also relieves anxiety and tension in patients without psychotic symptoms, as the following brief report will show.

METHOD OF STUDY

The Patients. The 188 patients in this study have been treated with fluphenazine since June 30, 1958. Of the total, 173 were inpatients and 15 outpatients; 170 were over 16 years of age and 3 were 14 years old. All had psychiatric illnesses, predominantly psychotic and acute. Therapy was continued in the majority of patients for 2 to 3 months, though a few were given the drug for less than 3 weeks. Medication was withdrawn in these last cases for a variety of reasons unrelated to its administration and usually of an administrative nature. Seven of the 188 patients have received fluphenazine for 5½ months and are still taking the drug. Four others have been on the drug for 4 months and at the time of report, 56 patients are receiving fluphenazine. Those patients who were not expected to benefit from a phenothiazine tranquilizer were excluded from the study.

The Medication. The dosage of fluphenazine varied from 1 mg. to 10 mg. daily, though 3 patients received more (15 or 20 mg. daily) for several days. The average patient was given 5 mg. immediately on admission, 5 mg. the next morning and 2.5 mg. each morning thereafter.

Throughout the study, fluphenazine was administered orally except in 19 cases where the drug was given intramuscularly for the first few days or weeks of therapy and thereafter administered by mouth. Injections were given in doses of 1 cc. (2.5 mg.) two or three times a day.

Other therapeutic aids such as psychotherapy, ECT, and change of milieu were employed in most cases. Barbiturates were frequently given at night to patients who required aid in sleeping.

Improvement in psychotic patients was evident by better behavior, diminished subjective symptoms, a more appropriate affect and less intense or no hallucinations or delusions. Improvement in patients without

psychotic symptoms was manifested by relief of anxiety so that they could function normally.

RESULTS

The results of treatment were as follows:

<i>Clinical Response</i>	<i>No. of Patients</i>
Excellent, or much improved	77
Good, or improved	64
Poor, or not improved	23
Discharged before final evaluation	24
Total	188

Within an hour after the first dose of fluphenazine the patients generally felt better and more relaxed. In most cases, a single dose in the morning sufficed to prevent a breakthrough of symptoms for the next 24 hours.

Extrapyramidal effects such as spasms of the shoulder girdle or neck were seen in some patients on 5 mg. daily and especially in those on 10 mg. daily, but these effects could be controlled by reducing the dosage. There were no other untoward reactions to the drug.

SUMMARY

Of the patients treated with fluphenazine, 141 of the 166 who were evaluated (85%) improved, 23 responded poorly, and 24 were for appropriate reasons not evaluated. The average dose was 5 mg. on admission, 5 mg. the next morning and 2.5 mg. thereafter as a single morning dose. Extrapyramidal effects were seen in patients receiving higher doses (5 to 10 mg. daily) but these were controllable by reducing the dosage.

Fluphenazine is an effective tranquilizer and is the most potent of the phenothiazines previously employed here, being about 25 times as potent as chlorpromazine. The rapid and sustained action of the drug and its administration as a single daily dose are distinctly advantageous.

THE DEVELOPMENT OF INTERCURRENT DISEASE AND INJURY IN THE TRANQUILIZED PSYCHIATRIC PATIENT

GORDON W. OLSON, PH.D., and DONALD B. PETERSON, M.D.

The known direct physical side effects of tranquilizing drugs are amply described but there has been little study of the indirect development of intercurrent disease or injury in the tranquilized patient. Because a previous study seemed to indicate a disproportionate amount of physical illness and injury in tranquilized groups this study was undertaken to investigate whether tranquilization was associated with admission to the infirmary.

The sample contained 143 infirmary admissions admitted over a 2 year period. From the medical records it was determined whether the patient had or had not been tranquilized *at the time of appearance* of the physical symptoms which eventually led to infirmarization. The percent tranquilized was compared with the comparable figure in the remainder of the hospital population.

RESULTS AND DISCUSSION

Forty percent of infirmary admissions were tranquilized at the time of appearance of their symptom as compared with 36% of the noninfirmary population. In the group aged 55 and over there was 41% tranquilization in the infirmary group as opposed to 28% in the noninfirmary group ($p < .01$), while of those aged 54 and under, the percentages of tranquilization were 38 and 51, respectively ($p > .05$). These results reveal an interaction of tranquilizing drugs and age and permit the inference that tranquilization of the psychiatric patient over 54 carries a greater than chance risk of development of disease or injury. When the data are graphed by decade of age it is apparent that this risk becomes manifest at about the age when many physiologists and physicians feel that physical decline becomes more manifest.

age 45 to 50.

We were unable to establish a relationship of infirmary admission to either drug derivative or dosage; neither were we able to demonstrate an association within the infirmary admissions between the fact of tranquilization and the physical diagnosis, but there was a trend in the data to suggest that a psychiatric diagnosis of organic psychosis was less compatible with tranquilization in the sense of development of physical symptoms.

Thirty-six deaths occurred in the elderly age group. Sixteen (36%) occurred in the tranquilized group and 20 (42%) occurred among the nontranquilized. The difference in death rates was not significant. Thus, tranquilization appears to be associated with the development of nontatal disease and injury.

At the present time we are inclined to entertain the hypothesis of a general non-specific factor associated with tranquilization which in the elderly group either favors, enhances, or produces physical illness or injury. Examples of such nonspecific factors would be decreased motility, decreased respiratory exchange, or decreased alertness.

We grossly tested an alternative hypothesis that the early manifestations of physical illness in the psychiatric patient may take the form of irritability, or other behaviors which might then lead to tranquilization, by investigating the incidence of infirmary admission concurrent with electroshock treatment in 17 individuals, aged 55 and over. One (6%) developed symptoms during ECT which resulted in admission to the infirmary. This indicated to us in a molar way that emotional disturbance as a precursor to physical illness occurs at best in a very small percent of the age group concerned. Allowing for this possibility and recomputing the statistics for tranquilization in the older age group produced a difference that was still significant ($p < .02$).

¹Read in full at the 115th annual meeting of the American Psychiatric Association, Philadelphia, Pa., April 27-May 1, 1959.

²Respectively, Chief Psychology Section, and Superintendent, Anoka State Hospital, Anoka, Minn.

SUMMARY

This study indicated a direct, statistically significant association between tranquilization of hospitalized psychiatric patients aged 55 and older and the development of physical illness or injury. This was not demonstrated for patients of 54 and younger. Dosage or drug derivative could not be related to the development of illness nor could physical diagnosis be related to

tranquilization. The data did suggest that tranquilization may be less compatible with the chronic brain syndrome than with other psychiatric conditions. We conclude that tranquilization of the psychiatric patient over 55 is associated with the subsequent development of nonfatal disease or injury of sufficient severity to warrant infirmary admission.

BLOOD GROUPS IN SCHIZOPHRENIA, ALCOHOLISM, AND MENTAL DEFICIENCY

STANLEY H. NORDMO, M.D.¹

Are blood groups related to mental disease? In 1939, Thomas and Hewitt(6) found no consistent correlation. Wiener(7) in 1948 cited numerous inconclusive studies from the earlier literature. Recently Lafferty and Knox(3, 4) found that white male schizophrenic patients were more apt to be Rh₀(D) positive, while Negro male schizophrenic patients had a greater frequency of Rh₀(D) negative than anticipated.

In view of these findings, a study of the patients at Colorado State Hospital was undertaken; 5,637 patients were classified according to diagnosis, age, sex and both ABO groups and Rh₀(D) type.

Individual blood donors listed with the Service League Community Blood Bank in Pueblo comprised the control population of 4,774. The results from comparison of the study groups and the control population were tested for statistical significance.

No correlation was established between schizophrenia (1,720 patients) and blood groups O, A and B and blood type Rh₀(D). The slight association between schizophrenia and blood group AB should be interpreted in light of the inadequate sample size.

There seemed to be an association between alcoholism (939 patients) and blood group A. The p value was .004.

There was no correlation between mental deficiency (482 patients) and either blood groups ABO or blood type Rh₀(D).

There appeared to be a correlation between the entire hospital population and blood group A. The fact that 2,496 patients were not included in the three groups studied could mean that one of the mental diseases excluded is associated with a greater frequency of blood group A. The diagnoses ranged from psychoneurosis to chronic brain syndrome.

The pitfalls encountered in a study of this kind are outlined by Manuila(5). He stresses that the normal variation in the ethnic and racial composition of samples may account for differences of 20% in the distribution of the blood groups. Then he mentions the sampling error which increases as the size decreases. The third problem concerns the technical error which in the past has varied from less than 1% to 9%. Wiener and Wexler(8) are also cautious in accepting the significance of many investigations of this sort.

In the present study, the sampling error is minimized in part by the relative size of the groups examined. The composition of the groups and the control population is fairly comparable in that the percentage of Mexicans in the hospital population is very similar to the percentage of Mexicans in the control population. It is probable that other ethnic groups are equally comparable.

The technical error based on the incidence of initially mistyped patients is 1.5%.

The possible association between blood group A and alcoholism is intriguing. Al-

¹ Colorado State Hospital, Pueblo, Colo.

though the male alcoholic patients outnumbered the female alcoholic patients 6 to 1, there is no difference between the sexes as far as the relative increase in blood group A is concerned. The number of alcoholic patients with Mexican surnames constitutes 25% of the total alcoholic group. As only 13.6% of the patients in the hospital have Mexican surnames and as blood group O predominates in this racial group, there seems to be further evidence to support the association between blood group A and alcoholism.

A common denominator in diseases which appear to be correlated with an increased incidence of blood group A may possibly be found in either the stomach or in the secretor status. Gastric carcinoma (1, 2) has been correlated with an increased frequency of blood group A. If the apparent increase in blood group A in alcoholics is confirmed, studies on the secretor status in both alcoholic patients and in those with gastric carcinoma should be conducted.

In summary, this study of the incidence of the ABO blood groups and Rh₀(D) type in schizophrenics, alcoholics and mental defectives tends to confirm the absence of

any correlation. There was no correlation between blood type Rh₀(D) and the three disorders studied. There seemed to be a significant association between alcoholism and blood group A. However the limitations of the study including the wide variations normally found in the incidence of blood groups, sampling errors and technical inaccuracy, underscore the rashness of arriving at definite conclusions on the basis of tentative findings.

A LONG TERM EVALUATION OF CHLORPROMAZINE IN SIX CHRONIC SCHIZOPHRENIC PATIENTS

PATRICIA NEELY WOLD, M.D.¹

This study is an attempt to isolate the chemical effect of one tranquilizer, chlorpromazine, from the other factors possibly related to the shifting mental status of 6 chronic schizophrenic patients. An effort is made to arrive at some conclusion about the relationship between maintenance therapy and the quality of adjustment made by these patients.

Six female chronic schizophrenic patients were chosen, all of whom had been inmates of a large mental institution where individual attention was minimal. All but one had been hospitalized 5 years or more

previous to medication and all had relatives who were still actively interested in them. Five of the 6 had been treated in the hospital for periods of time varying from 10 weeks to 12 months; one was medicated at the time of discharge. They were seen every 3 or 4 weeks for 10 to 15 minutes over a period of 3½ years, being told that the purpose of the visit was to regulate the dosage of medication. The dose was determined by the amount necessary to control symptoms. Notes were made on important events in the patient's life as told by the patient or a relative; likewise symptomatology was judged both by the verbal report of the relative and observation in the interview.

¹ Depts. of Psychiatric Research of the Mass. Mental Health Center and the Metropolitan State Hospital, Boston 15, Mass.

When each patient had been out of the hospital for one year, she was given a supply of placebos in place of chlorpromazine. If it was obvious that the patient was experiencing a relapse, she was told that the dose of the "medicine" would be raised. Relatives and patients were encouraged to feel that this was the solution. The patients were hospitalized when necessary, medicated with chlorpromazine, and discharged as soon as their mental status was the same as before the placebo had been given.

The placebo was instituted a second time when the patients had clinically improved to the pre-placebo level as reported by their relatives or as evidenced by their obtaining a job.

Five of the 6 patients responded to the placebo with a major relapse involving severe social disorganization. Since the experiment was repeated twice for each patient, this represents a total of 10 instances of relapse. It would thus seem very unlikely that the original improvement was related to the placebo effect, but rather to the tranquilizer, chlorpromazine.

There was a widely varied but individually consistent period of time after the institution of a placebo until the full-

blown relapse occurred. The relapse periods in the 5 patients were 5 days, 20 days, 2 months, 4½ months, and 5 months both times that the placebo was given. The length of time was not related to the dosage required to maintain equilibrium or to the mental status.

The major relapses did not seem to be related to events in the patient's life. Interpersonal tension which caused the patient difficulty on placebos was handled appropriately when chlorpromazine was reinstituted. In one patient who was difficult to keep adequately medicated, the form of the hallucination which occurred while she was on chlorpromazine, seemed to be related to interpersonal tension; however the symptom lacked the severe disorganization of the placebo relapses.

The relapses in 3 cases started with symptoms of tiredness and insomnia, and resulted in severe social disorganization in all patients, in contrast to symptoms occurring during medication. The patient who had the most symptoms while on chlorpromazine was the most difficult one to keep adequately medicated, thus suggesting that the occurrence of the symptoms was related to inadequate medication.

HISTORICAL NOTES

THE HISTORY OF ELECTROTHERAPY AND ITS CORRELATION WITH MESMER'S ANIMAL MAGNETISM

JEROME M. SCHNECK, M.D.¹

During the preparation of my book, *A History of Psychiatry*, I found a significant historical correlation (1) between some 18th century experiences with electrotherapy and animal magnetism.

A number of physicians were using electricity therapeutically in mid-century (2). Its application was not confined to them. John Wesley obtained an electrical apparatus about 1750 and issued a publication in 1759. It was claimed, at that time, that hundreds and perhaps thousands of people benefited from electrotherapy. Middlesex Hospital was the first teaching institution to acquire an electrical machine (1767), followed by St. Bartholomew's and St. Thomas's. An "asylum" in Leicester owned an electrical device for treatment of patients and in 1788 a special therapy room was set up in this connection. In 1793 a London Electrical Dispensary was organized and 3,000 patients were said to have been treated within 10 years, one-half cured and most of the remainder relieved of their symptoms. The history of electrotherapy in some form had long preceded these efforts. Therapeutic use of the electric eel can be traced to the Greco-Roman period (3).

While the electrotherapy movement was developing, Franz Anton Mesmer (1734-1815) was synthesizing his theory of animal magnetism and treating patients with claims of success. In 1779 he published the famous *Mémoire sur la Découverte du Magnétisme Animal* with its classic 27 propositions (4). Note numbers 21 and 22:

This system will furnish fresh explanations as to the nature of Fire and Light, as well as the theory of attraction, ebb and flow, the magnet and electricity. . . It will make known that the

magnet and artificial electricity only have as regards illnesses, properties which they share with several other agents provided by Nature, and that if useful effects have been derived from the use of the latter, they are due to Animal Magnetism.

Mesmer has been regarded by some as a brilliant innovator and by others as lacking in scholarship (5). It is often acknowledged, nevertheless, that his concepts can be linked with some trends of the time. For example, disease as related to fluidistic disharmony has been compared to the irritability theory of Albrecht von Haller (1708-1777) and the excitation theory of John Brown (1735-1788) among others (6). That Mesmer gave thought to underlying essentials when comparing therapies of his time is evident in the propositions mentioned above. His interpretation was clearly slanted in the direction of his personal theoretical preferences which is usually true of most innovators. Even disregarding Mesmer's theory we find that he was probably still accurate in the fundamentals of his observations. The therapeutic attributes of 18th century electrotherapy and magnetism possessed the common denominator pertinent to animal magnetism. This common denominator consisted of the essential ingredients of the transference relationship and its role in fostering therapeutic change, aside from any other aspects in the devices employed which might also be effective. This is consistent with observations today in connection with psychological factors in modern electrotherapy. Interest in the psychological aspects of today's electroconvulsive methods followed soon after their introduction (7).

Electrical appliances frequently elicit varying degrees of convulsive reactions, of course, and these are dependent on several variables consistent with the therapeutic intent of the physician. A point of interest

¹ Clinical Associate Professor of Psychiatry, State University of New York College of Medicine at New York City; Address: 26 West 9 Street, New York 11, N. Y.

is that Mesmer was obtaining, and apparently favored, the production of convulsive reactions, called crises, in many of his patients. They were regarded as beneficial therapeutically. They were evoked by what we would regard as psychological measures in the use of the *baquet* (the tub filled with glass and iron filings in contact with metal rods held by patients in group therapy) or in contacts with any "magnetized" objects. The convulsions must have had much importance psychologically for such patients in relation to the dynamics of their illnesses. Even now it is significant to note differences of opinion regarding the pertinence or necessity of convulsive reactions in ECT in relation to their psychological and physiological desirability within the therapeutic regime. Taking all of these facts and opinions into consideration, we may focus special attention now, in connection with the treatment of psychological illness or illness with known structural change in addition to psychological manifestations, on proposition number 23 :

It will be seen from the facts, in accordance with the practical rules I shall draw up, that this principle can cure nervous disorders directly and other disorders indirectly.

Allowing for changing concepts of "cure" Mesmer had something to offer. As for the historical development of scientific ideas, the correlation between his animal magnetism and the history of electrotherapy with their allied psychodynamic themes seems deserving of recognition.

COMMENT

GREGORY ZILBOORG

With the death of Gregory Zilboorg we record the loss of a good friend of many years. In Philadelphia at the 1959 meeting when we last saw him he was buoyant and active throughout the meetings. We knew that he had been seriously ill but we shared his hope that surgery he had recently undergone had cleared the way ahead. He was carrying on as if nothing had happened. He was not one to let health problems disturb his equanimity or, to the limit of possibility, his endeavor.

But the Fates were unkind. In a letter only two weeks before the end he wrote, with utter composure, of the unfortunate turn of events and the outcome he was approaching. "I am not doing any work to speak of"; he said, "I read a letter, I am cheerful. I don't even suffer moments of despondency." And so with even mind he finished his course.

A memorial of Dr. Zilboorg will appear in a later issue of the Journal.

A COLLABORATIVE RESEARCH PROGRAM BETWEEN SAINT ELIZABETH'S HOSPITAL AND NATIONAL INSTITUTES OF MENTAL HEALTH

The Clinical Neuropharmacology Research Center has been established at Saint Elizabeths to meet the long recognized need of the National Institute of Mental Health for a research center in a mental hospital setting and represents a collaborative research program between the two institutions, centered on the hospital. The main purpose is the study of the action of drugs on mental function and mental disorder.

The location of the Center at Saint Elizabeths Hospital was thought appropriate because here in a large and modern hospital abundant and varied clinical material would be available for clinical trials, as well as for special, intensive investigation of individual conditions and syndromes. Furthermore, it was thought desirable to expose investigators, working at whatever level or discipline, to the unique phenomena presented by mental illness in a mental hospital. These phenomena and their problems differ from, and are complementary to the picture usually presented by the private hospital, or the university clinic. It was therefore hoped that such mutual exposure would lead to the development of research and therapeutic tech-

niques applicable specifically to mental hospital populations; and to a more ready appreciation of the role of each in a common research program.

Essentially the plan is designed to break the deadlock of isolation between the scientist and the mental hospital, and the mental hospital and the growing points of the behavioral sciences. Also, the location of a research center within the Washington area, and within easy access of the Clinical Center in Bethesda should make for ready interaction between it and the resources and special services of the Clinical Center. The functions of the laboratories and clinical branches of the hospital, of the Clinical Neuropharmacology Research Center, and of the laboratories and branches of the National Institute of Mental Health in Bethesda are therefore envisioned as complementary and interdependent. A number of long range programs are planned, or in operation, with the active collaboration of these branches.

To ensure a clinical setting truly representative of the predominant hospital population, the Center was located in one of the older units of the hospital, the so-called William Alanson White Service. This is a

5-story building with some open and some closed wards, housing some 370 patients. The patient population is being steadily selected and sifted according to the needs of the research program.

Part of the ground floor, and the whole of the fifth floor of this service, were adapted for special research laboratories. The ground floor now includes laboratories of neurochemistry, neuropharmacology, electrophysiology, sensory physiology and neuroendocrinology. A laboratory to accommodate experimental animals for the study of the effects of drugs on animal behavior has been erected outside the electrophysiological laboratories. The whole of the fifth floor provides for the clinical parts of the program. Laboratories here include a small metabolic ward (complete with diet kitchen); clinical physiology laboratories; electroencephalographic and psychosomatic laboratories; psychometric laboratories; and a suite of rooms for interviewing, for long-term psychotherapy, for counselling, and for group therapy. On this floor are also the records and statistical offices (comprising modern data processing equipment) and offices for social scientists and secretarial help. All laboratories are finished and equipped according to the standards of the National Institutes.

At a more personal level, the day-to-day conduct of the Clinical research is carried out jointly by the staff of the Clinical Neuropharmacology Research Center and of Saint Elizabeths Hospital. Clinicians assigned to the Center by the N.I.M.H. work alongside their colleagues from the hospital, thus assuring closest possible contact with research problems.

The Chief of the Center serves as Director of Research of the hospital and Chairman of the hospital's Research Committee, whose function is to coordinate and promote clinical investigations in any part of the hospital and to submit to the Superintendent recommendations for their further development.

Research in a clinical area is inseparable from clinical care and, in the last analysis, it is the clinical care program that will reflect the usefulness or otherwise of its research program. There are already indications that the proximity of the basic sciences to the clinical area encourages the basic scientist's active interest in clinical problems, and the clinician's interest in scientific method. Moreover, as research techniques especially adapted to the study of clinical phenomena within a mental hospital are evolved they will take their proper place in the hospital training program and, it is hoped, thus lead to the creation of an academic setting within the confines of the hospital. The joint Saint Elizabeths-National Institute of Mental Health project could thus set a pattern for the future. Its measure of success, however, will inevitably depend upon the strength and evolution of the hospital it serves.

CORRESPONDENCE

THE QUESTION OF PSYCHIATRIC TRAINING ABROAD

Editor, THE AMERICAN JOURNAL OF PSYCHIATRY :

SIR : It has been said by Freyhan(1), and remarked by others(2, 3), that an American psychiatrist is apt to be struck by the differences in psychiatric theory and practice in foreign countries and that the foreign psychiatrist is often baffled by what he sees in the United States(4). Such differences have given rise to concern, even an admonition from Professor Bleuer(1), that they may result in the cessation of exchange of both communication and psychiatrists between America, Great Britain and the continent.

This situation is relatively new. In 1930 Mapother(5), having just returned from a visit to the United States, wrote that American psychiatrists "have the natural readiness to try anything once, but to me they seem neither credulous, nor given to making claims; in fact, they seem full of the 'enthusiasm without illusion' that is the true scientific spirit." Three years later in the 14th Maudsley Lecture, Adolf Meyer(6) spoke of the British contribution to American psychiatry. In the ensuing 15 years a number of British psychiatrists came to North America for postgraduate study, several returning to become the British exponents of the Feinsinger technic of short-term psychotherapy(7). And, in general, the exchange soon became more and more one-way, with few American psychiatrists going abroad for study and a feeling of separation becoming progressively more apparent. An English Professor(2) in 1953 referred to the differences in the evolution of British and American psychiatry as "differences . . . of quantity and tempo"; and several years ago another English psychiatrist(3), alluding to the growth of psychoanalytic psychiatry in the United States, made the comment that "a remarkable attempt has been made in many centers to ingest the whole system, python-like, into the body of academic opinion."

As a result of this separation, there has been in America, as Kanner suggests(8), a

loss of interest in basic clinical psychiatry and in the historical roots of modern psychiatry. Maciver and Redlich(9) have pointed out in a study of psychiatric practice not only a dichotomy in the theoretical orientation of American psychiatrists but also a relative lack of eclectics. And abroad, particularly in England, there has sprung up an intense distrust of psychoanalytic theories and psychotherapy in general(10). From this separation there have also arisen many distorted attitudes and conceptions, to the point that not a few American psychiatrists regard British and continental psychiatry as "descriptive" or, at best, existential; and *vice versa*, American psychiatry, as subjugated to an uncritical acceptance of psychodynamic theory and psychotherapy. Some effort has been made to bridge this gap in communication, especially in the areas of psychopharmacology and epidemiology; but little encouragement is given the American psychiatrist to obtain foreign training during his residency years. Few foundation grants, medical school travelling scholarships or governmental research or training stipends have been established for this purpose; and even in neurology where the tradition of a year's pilgrimage to the National Hospital, Queen Square, London, is long established, there are meager financial aids available. At best, there is the occasional medical society or academy of medicine which happens to have a scholarship or travel grant as a fossil from the days of the "American Medical Association of Vienna."

The value of foreign training in psychiatry has been stressed by many previous writers(11, 12, 13). But the lack of opportunity for such study cannot be emphasized or deplored sufficiently.

A STATISTICAL STUDY OF FIRST ADMISSIONS WITH PSYCHONEUROSES IN NEW YORK STATE, 1949-1951

Editor, THE AMERICAN JOURNAL OF PSYCHIATRY :

Sir: In his interesting article in the August issue of this Journal Malzberg states that the higher incidence of psychoneuroses among the Jewish population in comparison with other groups of our metropolitan population, such as Irish and Italian, has been attributed to the greater willingness by Jews to seek medical advice and, in particular, to a more favorable attitude towards psychiatry and psychiatrists. This is surely true and I believe that if we included the statistics about private psychiatric practice the incidence of psychoneuroses among Jews would be proportionately even much higher than calculated in Dr. Malzberg's study.

There is however a cultural conditioned

genetic-dynamic explanation for this discrepancy which can be proven statistically. The chief characteristic of psychoneurotic disorders (*Manual of Mental disorders* APA) is "anxiety which may be directly felt and expressed or which may be unconsciously and automatically controlled by the utilization of various psychological defense mechanisms. . . ."

The Jews as well as Irish, Italians and other population-groups have to deal with anxiety-producing problems. Besides becoming neurotic, there is another way of escape from "anxiety," namely to "narcotize" anxiety by becoming alcoholic. Now let us look at the racial differences of alcoholism as presented statistically by the Department of Mental Hygiene, New York State :

COMPARISON OF RACE DISTRIBUTION IN PRINCIPAL GROUPS OF MENTAL DISORDERS, 1951

<i>Mental Disorder</i>	<i>Per Cent of Total First Admissions of Each Race :</i>						
	<i>African</i>	<i>German</i>	<i>Hebrew</i>	<i>Irish</i>	<i>Italian</i>	<i>Slavonic</i>	<i>Mixed</i>
Alcoholic	7.2	5.0	0.5	12.1	2.8	6.7	6.5

There has been no remarkable change in these figures since that time. As a result of cultural factors the Jews do not use the escape of their anxiety-producing problems into alcohol to such an extent as the Irish or Italian. Although an increase of alcohol

use among the Jewish population has been observed the "psychoses due to alcohol" among Jews remains a "curiosum."

John Lanzkron, M.D.,
P.O. Box 1453,
Middletown, N. Y.

REPLY TO THE FOREGOING

Editor, THE AMERICAN JOURNAL OF PSYCHIATRY:

SIR: The statistics that Dr. Lanzkron presents are not as conclusive as he thinks. They are not rates of first admissions with alcoholic psychoses, *i.e.*, the number per 100,000 of each ethnic group, but percentages based upon total first admissions. The percentage may be high, but the rate may be low, or vice versa. Comparisons of the incidence of the alcoholic psychoses, as con-

trasted with psychoneuroses, are difficult to make because of the social factors which influence both treatment and hospitalization. Until a better measure of the true incidence of the psychoneuroses is available, hypotheses such as that suggested by Dr. Lanzkron are suggestive, but cannot be regarded as conclusive.

Benjamin Malzberg, M.D.,
Albany 10, N. Y.

A COMMENT ON SWEDISH PSYCHIATRY

Editor, THE AMERICAN JOURNAL OF PSYCHIATRY:

SIR: I was very surprised to read on page 83, vol. 116, July 1959, of *The American Journal of Psychiatry* a note according to which Swedish psychiatry is in a sad state and has not developed at the same rate as other special fields. Since I have had the chance to visit some Swedish psychiatric hospitals and all university clinics several times, particularly last spring, and to discuss psychiatry with Swedish psychiatrists exhaustively I should like to inform your readers with regard to my impressions. I found the standard of the Swedish mental hospitals I visited on an excellent level. They have been modernized from every possible point of view, and further modernization is planned. The back wards—always an important criterion for hospital care of the mentally sick—present a most happy homelike atmosphere. Occupational therapy is very well developed, the social life of the hospital patients is excellently organized. For the treatment of neurotic and "psychosomatic" patients there are splendidly equipped special clinics, wards and outpatient clinics. The social service for the patients is also well organized.

Pre- and postgraduate instruction in psychiatry is cared for very well and more time is given to it than in many other countries. Research work both in Swedish university clinics and in many Swedish state hospitals is carried out with the greatest exactitude. Publications on psychiatry are based on a vast quantity of clinical material and are conceived in a critical spirit. It is particularly impressive to see how much time many research students give to their studies before publishing them. It is not necessary to go to Sweden to recognize the pioneer research of Swedish psychiatrists in many fields, it is sufficient to look through the *Acta Psychiatrica et Neurologica Scandinavica* and its Supplements. It is correct to say that many Swedish psychiatrists follow trends in psychiatry which are not the same as in many other countries. This, however, does not lead to an isolation of Swedish psychiatry, but is on the contrary a very precious contribution to international progress in this field.

Prof. M. Bleuler,
Director of the Psychiatric
University Clinic Burghölzli,
Zürich, Switzerland.

Editor, THE AMERICAN JOURNAL OF PSYCHIATRY :

SIR : In the July issue of this Journal, Dr. Löfgren, in his comment on Prof. Kinberg's paper, referred to Swedish psychiatry as "barren and lacking in international contact" and stressed that its level was "not acceptable by modern standards." I have the privilege of some knowledge of Swedish psychiatry, and had the opportunity last winter to visit thoroughly all the university clinics and a number of other psychiatric institutions in Sweden. I feel it therefore to be my duty, as an independant observer, to make some comments on the paper by Dr. Löfgren, with whose opinion I strongly disagree. It is true that the late Prof. Sjöbrings psychopathology has still a great influence in Sweden. That holds true however only for certain universities and for certain aspects of his theory. His psychological "types" or, more exactly, "traits" system is considered as a convenient reference frame, and is now subjected to very thorough experimental researches, especially in Lund, using clinical, experimental psychological and somatometric techniques. Without going into details, Sjöbrings typology is not at all an "isolated" system, but has many connections with other European schools of thought (Pierre Janet in the first place). It is true too that psychiatry in Sweden is more somatically than psychodynamically oriented. I do not believe, however, that the somatic approach is so exclusive as could be inferred from Prof. Kinberg's paper and from Dr. Löfgren's letter. The development of clinical psychology in the last ten years is impressive, and the close cooperation between psychologists and psychiatrists, the support psychology receives from all the professors of psychiatry, and the scientific level of the papers published can compare favorably with the present state in the United States. Psychoanalytic concepts are not as widespread as in the United States, the number of trained psychoanalysts is small, but their proportion to the total number of psychiatrists is not

much below that in continental Europe. In the administrative, therapeutic, teaching, and research fields, psychiatry has attained in Sweden a very high level. The hospitals are generally extremely well planned and equipped, the State is presently providing large sums for their extension and modernization. There is a great concern about the social aspects of mental disease. The teaching at the graduate level is probably more extensive than in most European countries, and, in addition, series of lectures on medical psychology are given in the first years. Psychiatry is now considered in the medical schools as one of the main clinical subjects for the examinations, a situation probably unique in Europe. The level of research, as any reader of *Acta Psychiatrica et Neurologica* and of the published M.D. theses knows, is extremely high. The large amount of the material, the care in the clinical investigation, the planning of the experimental approach and of the statistical treatment, the thoroughness of the bibliography, are noteworthy. It is true that, with the exception of clinical psychology, the main lines of research are in the somatic field : biology of mental disease, biological therapy, genetics and population survey. In those fields Swedish psychiatry has gained international recognition. But it does not mean that Swedish psychiatry is isolated. Swedish psychiatrists are well acquainted with foreign literature, European as well as American. Many have travelled extensively and they are always open to new points of view. The contributions made by the present heads of university clinics and psychiatric institutions, as well as the work of younger psychiatrists are in themselves an eloquent proof of the originality of the Swedish psychiatric school. Originality is not a sign of isolation but of vitality.

Prof. agr. P. Pichot,
Hopital Sainte Anne,
Faculté de Médecine,
Paris (France).

NEWS AND NOTES

IOWA HONORS SEYMOUR VESTERMARK, M.D.—A bronze plaque honoring Dr. Vestermark has been mounted in the main corridor of the State Psychopathic Hospital according to Paul E. Huston, M.D., Chairman of the Department of Psychiatry and Director of the Psychopathic Hospital. This plaque reads:

In Memory
of

SEYMOUR DAY VESTERMARK, M.D.
State University of Iowa Medical Class of 1931
Born November 25, 1902
Died February 22, 1959

Distinguished graduate who, during 10 years as Chief of National Institute of Mental Health Training Branch, U.S.P.H., exerted a profound influence in the field of psychiatric training in the medical schools of the U.S.A.

DR. VISOTSKY HEADS CHICAGO MENTAL HEALTH SERVICE.—Dr. Harold M. Visotsky, assistant professor of psychiatry at the University of Illinois College of Medicine, has been appointed, effective Sept. 1, director of mental health for the City of Chicago. He will have charge of the mental health section of the Chicago Board of Health under the direction of Dr. Herman N. Bundesen, president.

Dr. Visotsky is the first full-time director appointed to this position. He has been coordinator of psychiatric training at the university since 1955 and consultant to the National Foundation, Polio Respiratory Center, U. of I. Hospital, as well as a consulting psychiatrist and a member of the educational faculty and committee in the residency training program at the Chicago State Hospital.

CORRECTION.—Information presented on page 171 of the clinical note entitled: "Drug Use-Rate in a State Mental Hospital" by John R. Whittier, *et al.*, American Journal of Psychiatry, 116, pages 169-171, 1959 is inaccurate. The two sentences preceding the summary, and the pertinent summary

content, should be corrected to read "By the end of the observation period, 61% of the total hospital population were receiving one or more of the drugs. Male patients on drugs represented 22% of the total hospital population, or 52% of the total male population. Female patients on drug represented 40% of the total hospital population and 68% of the total female population, all figures rounded to the nearest percentage point. Of the total, male, and female patients on drugs, 56%, 51% and 59% respectively were receiving chlorpromazine." As principal author, I am responsible for the inaccuracies in the percentage figures, which appeared during several revisions of the article prior to submission and were missed in final copy. I am indebted to the critical acumen of Matthew Kartch, 4th year medical student at Albert Einstein College of Medicine, for bringing the situation to my notice.

JOHN R. WHITTIER, M.D.
Director of Psychiatric Research
Creedmoor Institute for
Psychobiologic Studies

CONNECTICUT SEMINAR IN PSYCHIATRY, NEUROLOGY.—September 16, 1959-April 20, 1960. Sponsored by the Connecticut Dept. of Mental Health and the Dept. of Psychiatry of the Yale School of Medicine and in co-operation with other hospitals and training schools. Many eminent speakers and instructors have been engaged for each of the two sections of this seminar. This course is approved for Category 1 credit by the Academy of General Practice. For further information, address the Assistant Dean for Postgraduate Medical Education, 333 Cedar St., New Haven 11, Conn.

MASSACHUSETTS GENERAL HOSPITAL RESEARCH ON MENTAL RETARDATION.—A gift of \$1,000,000 from the Joseph P. Kennedy, Jr. Memorial Foundation for the establishment of the Joseph P. Kennedy, Jr. Laboratories for Research on Mental Retardation at the Massachusetts General Hospital has been announced. One-half will be spent for

the construction of the laboratories and the other half will serve as an endowment to provide continuing operating funds.

This is the first of the endowed scientific researchships planned under the Anniversary Program in observance of the 150th birthday of the Massachusetts General Hospital in 1961.

INDIAN COLLEGE STUDENTS' ATTITUDES TO MARRIAGE.—A questionnaire study was conducted by Principal H. K. Trivedi and associates of S. B. Garda College and B. P. Baria Science Institute, Navsari, India, and reported in *The Guardian*, the journal of those institutions, for March, 1959.

Of the 531 students volunteering 426 were men (24 of whom, married) and 120 women (7 married). The married students were all Hindus, 68 of the unmarried men from Muslim and Parsee minorities.

The students strongly favored completion of education before marriage. They also favored family planning and limiting the children (2 sons, 1 daughter). They realized the evils of the Dowry system. The women gave more importance to the social status of the spouse than did the men.

It is interesting to note that of the unmarried students 48% of the men and 55% of the women stated that they would not be prepared to take a spouse whose horoscope differed from their own.

This issue of *The Guardian* reports also the special features of the annual meeting of the College and Institute, honoring Professor Trivedi the founder of these institutions and who is responsible for their remarkable development. The occasion was especially notable by reason of the presence of His Excellency, Shree Sri Prakasa, Governor of Bombay State, who presented to Principal Trivedi, professor of philosophy and psychology, a handsomely bound *Festschrift* containing 73 tributes from educa-

tionalists and other eminent persons in various walks of life commemorating his 45 years of distinguished service to higher education.

NATIONAL ASSOCIATION FOR MENTAL HEALTH, INC.—The appointment of Lawrence J. Linck of Chicago as executive director of the National Association for Mental Health has been announced by the organization's president, Judge Luther Alverson. Mr. Linck has previously served as a professional management counselor with offices in Chicago, and as executive director of the National Society for Crippled Children and Adults from 1945 to 1956.

He has served as special consultant to the U. S. Public Health Service, and consultant to the Office of Vocational Rehabilitation in the U. S. Department of Health, Education and Welfare.

AMERICAN PSYCHOSOMATIC SOCIETY.—The Society will hold its 17th annual meeting at the Sheraton-Mt. Royal Hotel in Montreal, Canada, on Saturday and Sunday, March 26 and 27, 1960.

The Program Committee would like to receive titles and abstracts of papers for consideration for the program no later than December 1, 1959. The time for presentation of each paper will be 10 or 20 minutes.

Abstracts, of two or three pages, in 9 copies, should be submitted to the Chairman of the Program Committee at 265 Nassau Road, Roosevelt, N. Y.

Eric D. Wittkower, M.D.,
Chairman, Program Committee

Correction.—Three pages of plates illustrating the article by Dr. Nathan Malamud, pages 215 to 218 of the September Journal were, through a printer's error misplaced and inserted between pages 220 and 221.

BOOK REVIEWS

YEARBOOK OF NEUROLOGY, PSYCHIATRY AND NEUROSURGERY (1958-1958). By Roland P. MacKay, M.D. (Neurology), S. Bernard Wortis, M.D. (Psychiatry), Oscar Sugar, M.D. (Neurosurgery). (Chicago: The Year Book Publishers, 1959, pp. 623. \$8.50.)

Neurology. Among numerous developments of the year, Mackay puts first in importance the continuing investigation and differentiation of the neutropic viruses, of which the polioviruses are the most neurotropic. Reports on the Salk vaccine are "essentially unanimous in citing a 75% effectiveness against paralysis . . . [and] an immunity approximately as enduring as that from 'natural infection'."

Clinical and experimental studies reported in this Year Book, including reports of pathologic changes found in Hiroshima and Nagasaki victims, point up sharply the need of knowledge of radiation effects now and in the future.

Multiple sclerosis, although "one of the most actively studied of human diseases," is still a mystery, insofar as etiology is concerned.

Mackay calls attention to the publication of the "handsome and authoritative volume," *Neuropathology* by J. G. Greenfield and associates, and the lamented death of the senior editor.

Psychiatry. Psychopharmacology and physiologic treatment methods still occupy the predominant interest of psychiatrists everywhere. Wortis, in understatement, mentions 18 new drugs to be added to the list given in the last preceding Year Book.

The present status of insulin therapy was surveyed in the International Conference on Insulin Treatment in Psychiatry in New York City in the autumn of 1958 [This Symposium, edited by Rinkel and Himwich, is published by the Philosophical Library, 1959].

There is much research on biochemical abnormalities in possible relation to schizophrenia, but no generally accepted conclusions have been reached. There has also been increasing attention to the biochemistry of alcoholism.

Instead of trying to summarize the findings in a vast number of reports, Wortis gives a long bibliography (12 pp.) of publications in 1958 dealing with the several fields in psychiatry.

This section contains reports on psychiatry

in Asia and the Middle East, Germany, Portugal, Soviet Union, Finland and Denmark.

Neuropathology. Oscar Sugar directs the introduction to this section to a recasting of the nature of the symposium published in several Soviet journals. He refers to an article in *Science* (Oct. 10, 1958) that pointed out the necessity for evaluating Soviet neuropathology of having a thorough knowledge of the regional terminology of both languages and of the scientific slang. The reader must be aware of the necessity for a tolerance to official philosophy, including the worship of Party. Evaluation of Party doctrine is reported as part of psychotherapy in some areas.

The neurological and neurosurgical sections of the Year Book contain numerous short papers.
C. B. F.

BODY IMAGE AND PERSONALITY. By Seymour Fisher and Sidney I. Cleveland. Princeton, N. J.: D. Van Nostrand Co., 1958, pp. 420. \$9.25.)

If one reads between the lines of the research protocols, the scientific tables, and the statistical analyses in this volume, one finds the fascinating evolution of a research idea. The two authors, both psychologists at the Baylor University College of Medicine, had become interested in the concept of the body image, particularly as it relates to ego or boundary strength, and, in an initial study of patients with rheumatoid arthritis, they found that, of the several tests explored, the Rorschach test gave the most information regarding the body image. A review of the existing literature, which they summarize in this volume, revealed how little work had been done at the time on the manner in which the individual organizes perceptions about himself and about his body. The authors then launched into further research on how concepts about the body image might relate to personality structure, behavior, and site of psychosomatic symptoms.

Their first hypothesis, that patients with psychosomatic symptoms involving the body exterior would conceive of their bodies as surrounded by a protective, defensive wall, was supported by a series of studies of patients and their various psychosomatic disturbances. They also obtained evidence supporting their second hypothesis that the body image differences themselves played some etiological role in the choice of internal versus exterior symptom sites. When further studies on a group of normal

subjects substantiated these results, they proceeded to a number of validating explorations which indicated the consistency and significance of their measurements.

In a series of researches regarding personality and behavior, they found that high barrier scores correlated well with a higher level of goal-setting, a need for task completion, less suggestibility, freedom to manifest anger, self-expressiveness, greater tolerance of stress, a higher interest in work activity that involved personal communication, and that such persons were products of families where there occurred greater structuring of values and goals, with more interest in work and more stable marriages. Group studies indicated that their philosophy was characterized by firmness, definiteness, assertiveness, initiative, more leadership, and ability to talk. They were also more friendly and democratic, with greater humanitarianism.

A study of controls, neurotics, and psychotics revealed a decreasing barrier score as one proceeded towards the psychotic population. The authors follow this report with a discussion of the importance of the body image, its relationship to Freud's concept of the ego, and to the implications in the treatment of regressed schizophrenics, where attention to their body seems to be of paramount importance.

Further studies in family patterns revealed that low barrier persons are exposed to a family atmosphere that not only provides few definite identification models, but which is also characterized by relatively high insecurity and inappropriate rigidity. These people tend to see their parents in a threatening and fear-inspiring manner. Sex differences are revealed at different ages, in that lower scores occur in boys from 5 to 7, and in girls from 10 to 13, while in the intervening years they are the same. The authors relate this characteristic to Oedipal conflicts in the boys and earlier puberty in the girls. Cross-cultural studies indicated that high barrier groups were alike in that they permitted relatively later impulse satisfaction during the first few years of life than does the modern Western mode of civilization, that they provided the individual with more definite and less conflictual value models, but that they later demanded more rapid independence. With the Western tradition falling lowest on the barrier scale, searching questions inevitably arise.

Two more studies are reported. One finds a significant relationship between barrier scores and the location of cancer, while the other deals with various physiological manifestations. The most important of these was the study of general reactivity following the ideas of Fun-

kenstein, which indicated that high and low barrier individuals went in opposing directions in tests of various body reactions. An attempt was made to evaluate how these responses might be organized neurologically. It is known that passive personalities have a high alpha index in the EEG. The authors' investigation indicated that low barrier patients tended to be more passive and also had a higher alpha index. It was then speculated that high barrier individuals have a more elevated level of striate muscle excitation, and therefore may arouse more consistently the reticular formation through proprioceptive stimulation.

This book concludes with an excellent summary chapter. It also contains an appendix with certain Rorschach protocols, a bibliography of 360 items, and a subject and name index. This excellent work has brought much more clearly into focus another frame of reference for understanding personality development and function. It has presented much stimulating evidence, but, even more important, it has opened the doors to further research projects.

ERIC T. CARLSON, M.D.,
New York Hospital,

Cornell University Medical College Center.

PERSONALITY CHANGE AND DEVELOPMENT AS MEASURED BY THE PROJECTIVE TECHNIQUES.
By Molly Harrower, Ph.D. (New York: Grune and Stratton, 1958, pp. 383, \$10.00.)

Research minded practitioners will find this contribution quite challenging. Using her many years of experience, the author makes a serious attempt to discover answers to some intriguing questions concerning projective techniques. Some of these questions are: To what extent does projective material actually mirror reported change in behavioral adjustment and change in subjective experience? If positive changes are found, do they result from a dropping out of pathologic responses in the second test record, from an increase in positive indices of adjustment, or from a combination of both? How does an individual change during periods of normal growth and the passage of 5, 10 and 15 years? What about the similarities or differences in personality brought about through growth, maturation and life experiences on one hand, and various forms of psychotherapy on the other? What about changes introduced by psychotherapeutic techniques which are not found as a result of other experiences?

Raw data are provided in order that the reader may make personal judgments. Essentially, this volume is at the documentary level,

since the author believes that until there is sufficient evidence of what actually occurs, extensive theorizing is out of the question.

ARTHUR LERNER, Ph.D.,
Psychology Department,
Los Angeles City College.

EPILEPSIE. By J. A. Chavany. (Paris : Masson & Cie, 1958, pp. 353. 2.800 fr.)

This monograph attempts to deal with all the different aspects of epileptic disorders, although emphasis is placed on clinical manifestations. The first part of the book deals with the clinical description of epileptic seizures. The account of cases is colorful and precise. After dealing with the classical grand and petit mal seizures, the author describes the focal episodes or parietal, temporal and occipital origin. Much of the material is discussed in light of work done by Penfield.

The existence of a particular "epileptic personality" and an "epileptic dementia" is accepted by the author although the reasons for doing so are not clear. The underlying assumption seems to be that "essential" or "idiopathic" epilepsy is a disease entity *per se*, rather than a manifestation of some known or unknown etiologic process.

The author attempts to establish types of seizures which at times seem rather arbitrary and novel. For example "morpheic epilepsy" according to him is characterized by nocturnal attacks, frequent mental and endocrine disturbances and heredofamilial traits, whereas cases predominantly nocturnal but with an occasional diurnal attack are automatically eliminated from this group. Other sleep phenomena, like somnambulism, nocturnal terrors, transient abdominal pains and frequent dreams are somehow related to this entity called "morpheic epilepsy." The EEG is reported to reveal sharp waves, spikes or "trapezoid waves" in the temporal lobe and is held to be a "specific anomaly." Also it is not entirely clear from the text if the author believes narcolepsy and "narcoleptic epilepsy" to be one or two different entities, but after a brief discussion of the problem the conclusion seems to be that there are two different conditions and the best way to tell them apart is by a therapeutic trial. One would have desired a closer discussion of the pathogenesis as done in the past by Wilson, Adie, and others, instead of a general statement that there is a supposedly exaggerated "reactivity of the hypnic function" in epilepsy.

The epileptic phenomena of young children are treated in great detail. The author recommends not attaching the word "epilepsy" to just any convulsive episode in the young infant

for "humanitarian" and "practical" reasons since such a label may have painful consequences for the patient's future.

The concept of "late epilepsy" is also examined. In two thirds of the patients whose seizures begin after 25 the etiology can be determined, but in the remaining one third the cause cannot be established and hence the author would classify these as "essential epilepsy." A "true senile epilepsy" is described although difficult to separate this entity from seizures secondary to cerebrovascular disease.

The hereditary aspects of epilepsy are based on the author's vast clinical experience. The work of Lennox on twins is amply quoted. The conclusion is that "essential epilepsy" although a disease entity, is not inherited as such but only as a predisposition to convulse regardless of the etiology.

The chapter on EEG is excellent and the treatment of the differential diagnosis is adequate. When dealing with syncope and related conditions, there is no mention however of the "tussive syncope" or "ictus laryngeus." When discussing "functional hypoglycemia" the author states that this disorder occurs in poorly nourished individuals, which is not the experience of the present reviewer.

It is unfortunate that such a comprehensive and informative monograph should be marred by minor oversights. There is a complete absence of illustrations and figures. Another instance is that quotations from the French literature are given full bibliographic notice while work published in English or German, except for a single note in page 272, is usually mentioned without reference.

The book however, is an outstanding piece of clinical insight and will prove to be of invaluable assistance to the neurologist, the internist and the general practitioner.

JOSE M. SEZARRA, M.D.,
Boston, Mass.

THE CRIMINAL MIND. A Study of Communication between Criminal Law and Psychiatry. By Philip Q. Roche, M.D. (New York : Farrar, Straus & Cudahy, 1958, pp. 299, \$5.00.)

By his work in forensic psychiatry and by his writings Dr. Roche has gained the confidence of the courts and of the legal profession in Pennsylvania. From 1934 to 1945 he did psychiatric work at the Eastern State Penitentiary in Philadelphia. As a witness in court he is held in high regard by lawyers, and judges have sought his advice on sentencing. In an interesting paper "Dr. Woodhouse Meets Daniel McNaghten" he pointed out a shocking

miscarriage of justice caused by disregard of elementary psychiatric facts: a physician who suffered from a psychosis with delusions was nevertheless found guilty of murder in the first degree.

The Criminal Mind is an expanded statement of the Fifth Annual Isaac Ray Award lectures delivered by Dr. Roche at the University of Michigan in 1957. It is a survey of the theoretical problems of forensic psychiatry frankly focused on "the subjective element of crime." As the book's subtitle states, the author examines especially the question of the communication between criminal law and psychiatry. A good deal of recent literature is carefully considered and pertinent cases are discussed. Some of them the author saw himself; others include the Gibbs case in which the late Dr. Strecker testified, which is well described in Richard Gehman's *A Murder in Paradise*.

Dr. Roche has a definite point of view which he sets forth clearly: he has come to the conclusion that the use of psychiatry as part of the public adversary system of criminal justice should be strictly limited or abolished, while its function in pre-trial and post-trial phases should be enlarged. He is most pessimistic about any useful role for the psychiatrist in the courtroom. The use of psychiatry should be restricted, he feels, to these aspects of the administration of criminal law: "(1) advisory on the question of triability of the accused, (2) informative and advisory leading to appropriate disposition of the convicted, (3) provision of techniques for changing convicted persons in the direction of self awareness and reform, and (4) advisory on questions of release of convicted persons."

One of Dr. Roche's theses is that criminals and mentally ill persons are not basically different, but differ only in the manner we deal with them. He finds that the law is public-centered, while psychiatry is individual-centered. His view of the essential relation between law and psychology is family-centered: "The law takes over where the parent leaves off" and "... criminal justice is a continuation of child-rearing indoctrination. ..."

Because it discusses the relevant questions fairly and clearly, Dr. Roche's book can be read with profit by both psychiatrists and lawyers. Throughout his exposition he is not controversial in any way. But the subject matter itself inevitably is controversial. In fact, forensic psychiatry at this time is the most crucial point of controversy in psychiatry. What we disagree about is not so much opinions as facts. Ninety percent of what is discussed in

theory is dynamically and psychoanalytically oriented, as in this book. What is actually practiced in trials and prisons, however, is 90% based on a psychiatry which recognizes only 3 or 4 diagnoses—and those only when they lead to totally disabling and deteriorating conditions. This psychiatry, or alienism, is more rigid and antiquated than the McNaghten rules of the lawyers. Just now a young man clearly suffering from catathymic crisis was permitted to commit suicide in the Massachusetts death house.

Like many other psychiatrists, the author condemns the McNaghten rules totally and unconditionally. Long experience has taught me, however, that many other things come first, before a change in the legal definition of insanity can do any good whatsoever. I have taken comfort from the fact that men like Sir Norwood East, Professor Jerome Hall and Dr. Clarence B. Farrar share this view. Unfortunately serious books like this by Dr. Roche are conditioning judges and the legal profession to accept subjective and highly individualistic reasoning. That interferes with democratic justice: A more objective and strictly social orientation would be necessary: clinical facts instead of speculations. As far as the role of the psychiatrist in the trial is concerned, it is of course not easy for psychiatrists used to sitting behind a couch or an electroshock machine to testify from a witness stand in court. They find it hard to forego their highly individualistic authoritarianism. But do not the often friendless and moneyless mentally diseased persons who have fallen into crime need somebody in the trial to fight for their right to live?

The Isaac Ray lectures so far have predominantly leaned toward the point of view expressed by Dr. Roche. They have not faced the grave abuses of psychiatry, and have leaned heavily on the subjective and individualistic side, finding more to criticize in the law than in the present state of psychiatry itself. The point of view of the as yet small minority which demonstrates by clinical research the dialectic interaction between conscious, unconscious and social forces in the causation of crime, has never found expression in these lectures. Perhaps it is good so. Perhaps the super-analytic, super-individualistic trend will have to run its course before a more strictly objective clinical and social standpoint is necessitated by the very jungle of legal insanity which now prevails.

FREDERIC WERTHAM, M.D.,
New York, N. Y.

THE DIVINE WIND: JAPAN'S KAMIKAZE FORCE IN WORLD WAR II. By Rikihei Inoguchi, Tadashi Nakajima, and Roger Pineau. (Annapolis: United States Naval Institute, 1958, \$4.50.)

In the last 9 months of World War II there occurred one of history's greatest mass suicides. Twelve hundred and twenty-eight Japanese Kamikaze pilots flew their bomb laden planes on one way flights to crash bomb—or attempt to crash bomb—them into U. S. battleships. Here was suicide which, as much as any, demonstrated the wish to kill and the wish to be killed, and which was unsurpassed in modern Japanese history. The Japanese "near death" tactics of a "death-defying" unit blockading Port Arthur in 1905, and midget submarines attacking Pearl Harbor in December, 1941, had left survival chances for the "death-defying warriors." With the Kamikazes there was only the certainty that the pilot would die. The Japanese Banzai charges had been suddenly ordered, swiftly executed, leaving the suicider little chance to dwell on his fate. The Kamikazes were systematically organized, and were protracted over a period of months. An American Admiral, in his foreword to this book, recalls, "Among those of us who were there, in the Philippines and at Okinawa, I doubt if there is anyone who can depict with complete clarity our mixed emotions as we watched a man about to die—a man *determined* to die in order that he might destroy us in the process. There was a hypnotic fascination to a sight so alien to our Western philosophy." The "hypnotic fascination" was that, however "alien," the Kamikazes originated in the death instinct that Freud had postulated is in all of us.

How, in this instance, did the death instinct gain such dominance? Written by 2 Japanese officers who helped organize the Kamikazes, this book is undistinguished in literary style and shuns any psychological probing. Yet it adumbrates more fully than any previous English account the topical conditions and some of the forces of Japanese culture which fused to replace the will to live by a will to die.

Kamikaze is named for the "Divine Wind" that had saved Japan from Mongol invasion in 1281. In October 1944, when the Americans were invading the Philippines and Japanese defeat loomed, Admiral Onishi, an old veteran Japanese imperialist, formed 23 young veteran Japanese fighter pilots into the first Kamikazes. The pilots had seen most of their comrades killed in combat, and confronted by proliferating American planes and skilled American pilots, had felt increasingly impotent. Onishi

first told them that their suicides would potentially turn the tide of events and achieve victory. He then dubbed the pilots "gods without earthly desires" (hence immortal), now the most important people in Japan, whose deeds would be immediately reported to the Emperor and nation, and then inscribed in the Yasukuni Shrine to Nippon's departed warriors. Five seconds after hearing Onishi's plan, Lt. Seki, chosen to lead the first Kamikazes, replied without the slightest falter, "You absolutely must let me do it." And most of the first 23 seemed to have been equally enthused.

After the loss of the Philippines, Onishi, no longer promising victory, could only tell the Kamikazes: "Even if we are defeated, the noble spirit of this Kamikaze attack Corps will keep our homeland from ruin. Without this spirit, ruin would certainly follow defeat." The first eager 23 fliers, now dead, were replaced by raw, inexperienced men. "Coercion" was used to recruit them—we are not told just how this operated, and many of these recruits were "disturbed" over the idea of dying; again we are not given details. In the end, we are told, these disturbances were resolved and replaced by a sort of mania and eagerness to die. Before final flight there was the final gesture of a glass of wine and a rare final good meal.

Although we are not given psychological profiles of any of the pilots, it seems that, in the absence of any hope of victory, an important factor which made men Kamikazes was the Confucian precept of unquestioning obedience to elders and superiors, which, in Japan, had been perverted to maintain a rigid caste. In the small selection of last letters home to parents, while there is no mention of wife or sweetheart, there is a constant play of gratitude to the parents, a sense of not having performed well for them that now, responding to Admiral Onishi's summons, will be rectified. Wrote one pilot: How I appreciate the chance to die like a man! . . . thank you, my parents, for the 23 years during which you have cared for me and inspired me. I hope that my present deed will in some small way repay what you have done for me." There is a suggestion that hostility to a parent may be expressed in a Kamikaze act: a pilot "brought up by a step-mother, his youth had not been a particularly happy one" writes his father: "as death approaches my only regret is that I have never been able to do anything good for you in my life . . . During my final plunge, though you will not hear it, you may be sure that I will be saying 'chichiue' (revered father) to you, and thinking of all you have done for me."

By August 1945, the 1,228 Kamikazes had

sunk 34 U. S. ships, damaged 288, taken a heavy toll of U. S. life, and completely failed to halt the American advance. Then the Emperor ordered surrender and Onishi committed hari-kari.

Thanatos versus Eros! After the war Japanese Eros reacted against Kamikaze Thanatos, and many Japanese criticized the Kamikazes. Wrote the Japanese philosopher Suzuki: The Japanese military, in asking the people to obey them, presented them with the Samurai ideal of killing and dying, with ideas of "divine glory of his Majesty" "the Divine nation" "the Holy war," with gods of war, all of which were the products of Japan's insularity. But, writes Suzuki, the military neglected or ignored such truly universal ideas as "love, humanity, and mercy." Yet, in 1959 a Tokyo psychiatrist, Dr. Tsunehisa Takeyama, pointed out that in Japanese culture the Thanitos, which produced the Kamikazes, is today responsible for Japan's high rate of suicide. Though Japanese youth no longer commit suicide in airplanes, in the 15-25 age group (the age group of the Kamikaze pilots) suicide, taking precedence over death by accidents and tuberculosis, is the leading cause of death.

PROGRESS IN PSYCHOTHERAPY, VOL. 3: TECHNIQUES OF PSYCHOTHERAPY. Edited by Jules H. Masserman, M.D., and J. L. Moreno, M.D. (New York: Grune and Stratton, 1958, pp. 324. \$8.50.)

By this time the rationale for the publication of the annual volume on progress in psychotherapy scarcely needs explanation or justification. These selections from very broad areas in an even broader field provide the busy psychiatrist with an excellent, well-chosen cross-section of modern activities and thinking in the admittedly difficult and confusing field of psychotherapy. In this reviewer's opinion, Drs. Masserman and Moreno have constantly done an excellent job in selecting significant material and arranging it in such a way as to make it useful to the reader.

As in previous volumes, the present one is divided into several parts: in this case, "History," "Rationale and Methods," "Special Techniques," "Psychopharmacology," and "Developments Abroad," with, of course, author and subject indices covering the entire volume.

In the first section on the history of psychotherapy, Drs. Vieth and Lewis provide 2 articles which concisely summarize the history of psychotherapy with some new and colorful

anecdotes on temple inscriptions and descriptions of mental disorders.

In the second section, "Rationale and Methods," the articles by Frank and Diethelm really belong together since they have to do with dynamic psychotherapy, particularly as it relates to the interreaction between the therapist and the patient and the biases which each brings to this relationship. Ehrenwald takes up another aspect of an area in which both Dr. Frank and Dr. Diethelm have indicated some interest; namely, the problems of scientific methodology in psychotherapy. The use of the family group and family therapy and the general problem of the social aspects of psychotherapy in the United States are covered in the articles by Ackerman and Behrens, on the one hand, and Redlich on the other. All these papers have in common a very important emphasis on the desirability of eliminating doctrinaire influences wherever these are found to operate against the vitality which should be the essence of psychotherapy.

The last paper in this section on psychodrama by Moreno could have been placed in the next section, but since it deals with fundamental rules of psychodrama, probably could justifiably be included here. The detailed discussion of various psychodramatic techniques and some definitions of specific sub-techniques, will prove interesting to most readers.

In the third section on special techniques, there is a smorgasbord which ranges from linguistics through projective tests, music therapy, dance therapy, and such matters as psychotherapy from the point of view of nursing and marriage counselling, and moves on into such special fields as psychiatry and the ministry, the psychiatry of the adolescent, "bifocal" group therapy, and the special problems of rehabilitation and military service. Various matters are admirably discussed in a series of short articles by extremely competent authors.

The anthropological approach which is discussed in a short paper at the end of this section, actually concentrates on a very small portion of the anthropological approach as might be expected in a section which attempts to provide the reader with a taste of the various approaches. It is, however, useful to consider anthropology in connection with the specific problems of marriage and the use of this point of view in evaluation of clinical material.

In Section Four, "Psychopharmacology," there are excellent summaries of the various present developments in psychopharmacology and in the biological and pharmacological aspects of schizophrenia. Of considerable general

use are articles by Kurland on the placebo, and Wickler on the methodology of research.

In the last section there are 6 papers dealing with developments abroad, the first of which is general in flavor, the others being specifically directed at situations in various countries. This is a move in the direction of psychiatric understanding across borders which justifies a good deal of underlining and emphasis in all of our literature. Dr. Masserman, in his summary of the section on psychotherapeutic progress in Latin America, makes an eloquent plea for better interchange of written communications, better translation services, and increased visits by psychiatrists of the various countries so that communication can be improved and maintained.

In essence, this volume of *Progress in Psychotherapy* continues to provide a useful service to readers in psychiatry and is a worthy addition to the series of volumes edited by Drs. Moreno and Masserman.

PROGRESS IN PSYCHOTHERAPY, VOL. 4 : SOCIAL PSYCHOTHERAPY. Edited by Jules H. Masserman, M.D., and J. L. Moreno, M.D. (New York : Grune and Stratton, 1959, pp. 361. \$8.75.)

The fourth volume in this series is now available and its contents include an introduction by J. L. Moreno; sections on Fundamentals of Psychotherapy ; Methods of Social Psychotherapy ; Special Techniques ; Developments Abroad ; and a final section, Review and Integration, consisting of an article by Jules H. Masserman, "Science, Psychiatry and Religion." The intervening four parts contain more than 35 articles by specialists in psychotherapy.

A.C.

SELECTED WRITINGS OF JOHN HUGHLINGS JACKSON. Edited by James Taylor. 2 vols. (New York : Basic Books, pp. 500 and 510. \$15.00 the set.)

From the middle of the 20th century it is difficult to comprehend the magnitude and importance of the contribution of John Hughlings Jackson. In 1859, at the age of 24, he went to London, uncertain whether he should practice medicine or study philosophy. Fortunately he did both, becoming interested in the organization of the brain and the relationship between structure and function.

Jackson arrived in London at the beginning of the revolution of medical thought that gave birth to modern scientific medicine. Virchow had published his *Cellular Pathology* the preceding year, but the work of Pasteur and Koch

was still a decade away. During the year that Jackson moved to London Darwin published *On the Origin of Species*, which caused a philosophical and theological controversy that is still reverberating. That same year the National Hospital, Queen Square, was founded, but it was not till 1862 that Hughlings Jackson was appointed to its staff. Even before this his interests were directed toward the nervous system. At that time nothing was known of cerebral localization, and Jackson's conclusions regarding the motor cortex antedated by several years the experimental demonstrations by Fritsch and Hitzig. Jackson's careful, systematic observations, coupled with his brilliant interpretations of their significance, quickly placed him in the forefront of neurological thought. He was not content to report isolated facts, but utilized his philosophical training and produced an integrated concept of the relation between brain, mind, consciousness and body.

This philosophical approach has had a widespread influence on neurological thought, while his writing on the organization of the mind and levels of integration form the basis for much of the modern psychiatric theory.

Jackson published more than 350 papers, many of them in obscure journals with a limited circulation, so that much of his work is not readily available. Realizing the importance of his contributions two volumes, amounting to about 1,000 quarto pages, were published by James Taylor in 1931. The demand was large and it has been out of print for several years. The republication of these volumes emphasizes the importance of Jackson's work. Although some of the details of his physiological conclusions are no longer accepted, his views upon the organization of the mind and its relation to the nervous system are valid. Every neurologist and psychiatrist will find a study of these papers quite rewarding.

JOHN SCOTT, M.D.,

Toronto, Can.

VERDICT FOR THE DOCTOR. By Winthrop and Frances Neilson. (New York : Hastings House, 1959, pp. 1x + 245 incl. bibliogr. and index. \$4.50).

This is the story of a *cause célèbre* of particular interest to physicians, lawyers, journalists, sociologists, and any one who would like to read a profoundly moving story that happens to be true. It is of special interest to psychiatrists because it is the case of Benjamin Rush, who after long enduring malicious attacks in

print by an English free-lance writer, William Cobbett, finally brought suit charging libel, and was vindicated.

The case came to trial before the Supreme Court of Pennsylvania, Friday, December 13, 1799, in the celebrated State House, now Independence Hall.

The main issue was Rush's theory of treatment—heroic purging and copious bleeding—particularly as practiced by him during the frightful yellow fever epidemics in Philadelphia in 1793 and again in 1797. "The times are ominous indeed, when quack to quack cries purge and bleed!" This statement, with obvious reference to Rush, was quoted from Cobbett's writings by plaintiff's counsel during the trial. Defence counsel argued that this and many other intemperately abusive expressions used by Cobbett were not intended as personal attacks on the doctor but on his system of medicine which not only the defendant but some of the well known doctors of the community condemned. This was a weak defence however in the light of another quotation from Cobbett's writings referring to Rush: "I will persecute him while living, and his memory after death."

Cobbett was a fiery tempered Englishman who was most happy when he could attack some one or some thing. He had set up a printing establishment and bookstore in Philadelphia and brought out a periodical publication which he called *Porcupine's Gazette*. He had adopted the pen name Peter Porcupine as fairly suited to his personality. Freedom of speech and freedom of the press received exaggerated reverence at that period in American history, and Dr. Rush and his family had been caused untold suffering by the venomous assaults in *Porcupine's Gazette*. No credit was

given to the fact that during that awful summer of 1793 when all who could were fleeing from the afflicted city, Benjamin Rush was one of the few who remained at their posts, suffered himself from the contagion, and in entire ignorance of the cause of the epidemic, applied the measures he considered to be empirically the most useful.

When the evidence was all in Judge Shippen's charge to the jury amounted to conviction of the defendant, who five days before the trial had left his case in his lawyer's hands and fled to New York. The judge pronounced: "The counts laid in the declaration are fully proved by the publications, which are certainly libelous. . . . The liberty of the press, gentlemen, is a valuable right in any free country, and ought never to be unduly restrained. But when it is perverted to the purpose of private slander, it then becomes a most destructive engine in the hands of unprincipled men." He instructed the jury that it was proper to give not only "compensatory, but exemplary damages, thus stopping the growing progress of this daring crime."

It was candle light when the jury returned.

"The verdict of the jury was in favor of Dr. Benjamin Rush, in the sum of five thousand dollars."

Cobbett in New York became only more embittered. He started another newspaper which he called the *Rushlight*, and continued his attacks on Rush more venomously than before. Threatened however with further legal action he found it expedient to return to England, where after various ups and downs, including two years in Newgate Prison on a charge of sedition, he eventually became a member of Parliament.

C. B. F.

THE ACADEMIC LECTURE

HOPE

KARL MENNINGER, M.D.²

INTRODUCTORY REMARKS

President Gerty's invitation to address this assembly of the future leaders of our Association was one of the great pleasures and honors of my life.

I can well remember my excitement when, in company with my father and my teacher Ernest Southard, I attended my first annual meeting—the 75th anniversary. This was 40 years ago, here in Philadelphia. I think I have missed only one meeting since then. In those days we were a small, intimate, informal group of a few hundred; everyone knew everyone. The program was simple, the entertainment lavish and the whole meeting a kind of family reunion. Southard and father and many others are gone now—but there are new elements of a family affair for my brother Will and myself of which we are proud.

In the years since then there has been a vast development in the numbers and complexity of our organization. I am glad to have had a part in the planning for its re-structuring, even though the immediate impact of the suggestions made by the Committee on Reorganization was a shock reaction. That 14 of our 16 recommendations have been put into effect is gratifying. But I find the greatest satisfaction in the emphasis which the program committees and officers have placed on our continued self-improvement, on psychiatric education, on, for example, academic lectures!

It is from a background of teaching that the topic which I propose to discuss emerged. I would like to warn you not to expect a scientific analysis of it along conventional lines. The subject does not permit of that; we don't yet know enough about it, and it would be presumptuous to make the attempt. I am not reporting a

research or a discovery, and it is no dark hour, calling for exhortation or comfort. I speak, rather, to the point of focussing attention upon a basic but elusive ingredient in our daily work—our teaching, our healing, our diagnosing. I speak of hope.

Long before love became medically respectable, long before Sigmund Freud demonstrated it to be a basic consideration in psychiatry, philosophers and poets and the common people of the world knew that it was essential to our mental health. Perhaps the most beautiful essay ever written was about love and its manifestations in personality.

To that essay is appended a footnote which is often quoted as if it were a summation. True, observed the writer, there are other permanent goods in the world beside love: there is faith, and there is hope. But, he added, "the greatest of these is love." With this concluding phrase most psychiatrists, I presume, would agree. Most of us, I think, would also agree to include faith—the faith that sustains our conviction that what we are doing is worth doing, the faith that our existence has meaning and the faith that our concern for one another reflects the concern of a Creator.

Our shelves hold many books now on the place of *faith* in science and psychiatry, and on the vicissitudes of man's efforts to *love* and to be loved. But when it comes to hope, our shelves are bare. The journals are silent. The Encyclopaedia Britannica devotes many columns to the topic of love, and many more to faith. But hope, poor little hope! She is not even listed.

I confess I was astonished to discover this. And yet, I realized that this avoidance of the theme reflected my own attitude. Time was when for this occasion I should have chosen as my subject "Love" or "Hate" or "Conflict" or "Instinct" or "Sub-

¹ Read at the 115th annual meeting of The American Psychiatric Association, Philadelphia, Pa., Apr. 27-May 1, 1959.

² The Menninger Foundation, Topeka, Kan.

limitation" or "Symptom Formation"—but never such a thing as "Hope." It seems almost to be a tabooed topic, a personal matter, scarcely appropriate for public discussion. And yet—since when has psychiatry eschewed examination of our innermost thoughts and feelings? Should we not adhere to our professional habit of self-examination and contemplation? If we dare to hope, should we not dare to look at ourselves hoping?

This is not the way I began to think about the topic. Nor did I come to it fresh from struggles with Kierkegaardian logic, or from brooding over Greek pessimism, or from apprehensiveness concerning the muddled management of unsettled world affairs. It was all in the day's work, so to speak, some preoccupations with the motivations of the young doctors I teach. The miracle of growth has long intrigued me: the growth of the child, the growth of plants, the growth of cultures and the growth of young psychiatrists. I have seen one after another young doctor step forward, fresh from his internship or from his military duty, to enter the mysteries of psychiatric training. I have seen these young men approach the abstruse and puzzling material of our field of medicine with resolute courage—let us say, rather, with hope.

But behind the façade presented by these acolytes there are often tumults of conflicting voices, fearful insecurity and bold over-self-confidence. The dramatic picture of psychiatry fascinates them, the reputed resistance to treatment challenges them, the multiplicity of method appalls them. They are assigned to wards filled with vacant or frantic faces, turned now upon "the new doctor." It is usually long after their initiation into the uncanny world of mental illness that they can distinguish the moving process, or would have the personal experience of interaction with a recovering patient.

Nevertheless, the novitiates assail their tasks headlong, sometimes with a *furor therapeuticus*. There is nothing mercenary or aggressive about this. They are not working for money. They are struggling to become effective in a new kind of relationship with patients. Sometimes they go too

far, they presume, they expect or promise too much. More often frustration, sad experience, or self-depreciation erodes the confidence required for persistent effort and the little candle of hope, which to awhile burned so brightly, weakens, sputters and goes out. We see the beginning of a repetition of scenes so common 25 years ago—hopeless physicians presiding, passively, over hopeless patients. "Psychiatry," we will hear, "has been oversold. The enthusiasm of inexperience only awaits the disillusionment of time. It is enough if we bestow kindness and wait for the inevitable. Hope is for the hopeless, and for fools."

We would like to think that the young men who pass through our training programs mostly emerge with certain limits put upon their expectations and certain guards upon their implied promises, but with the flame of their hope unextinguished and unextinguishable. We like them to believe that there is no patient for whom something helpful cannot be done. But we also like them to realize that the changes the patient desires in himself, or the physician desires in his patient, may not be the ones which come about, may not even be, in the long run, the changes that it were best to have sought for. It is a responsibility of the teacher to the student, just as it is of the young doctor to his patient, to inspire the right amount of hope—some, but not too much. Excess of hope is presumption and leads to disaster. Deficiency of hope is despair and leads to decay. Our delicate and precious duty as teachers is to properly tend this flame.

I propose, therefore, that we examine this essential constituent of both treatment and teaching. How shall we think of it? Is it something which *deserves* our concern as scientists? Or only as philosophers and poets? Is it only an epiphenomenon of life and the healing art? Do we, perhaps, tacitly ascribe hope to temperament, a sort of fringe benefit deriving from certain fortuitous congenital arrangements of glands and neurons? This is slight improvement upon the humoral theories of sanguinity and melancholy treasured by our forebears. If we ascribe hope, as some psychoanalytic writers have done, to recollections of maternal infallibility and recurrent oral grati-

nections, what combination of these experiences shall we regard as optimum? Others have seen in hope a prevailing note of fear, a counter-phobic denial of the horror and despair born of self-destructive trends or of the immanence of existential doom.

More congenial to my thinking is the ascription of hope to the mysterious workings of the repetition compulsion, the very essence of which is a kind of relentless and indefatigable pursuit of resolution and freedom. I would see in hope another aspect of the life instinct, the creative drive which wars against dissolution and destructiveness. But some will say, with Freud, that this is only our speculative abstractions to supply a model for practical thinking and behavior. Our mythology, he called it.

Here we might pause a moment to consider another mythology about hope. Pandora, it will be recalled, was an agent in the infliction of revenge of mankind by an angry Zeus. Curiosity led to her opening the box from which all the evils now in the world emerged. Biting, stinging creatures flew through the air and attacked mortals, but remaining behind was one good little sprite, man's consolation, Hope. But if Hope was a blessing, why did she remain in the box? And if, on the other hand, she was an evil like the rest, perhaps even the worst evil of all, why did she not fly out with them and begin work?

The Greeks mostly did consider hope an evil. The Greek philosophers and the later Greek literature tended more and more to the view that since fate was unchangeable, hope was an illusion, "the food of exiles" (Aeschylus) and, indeed, "man's curse!" (Euripides). Quotations from Solon, Simonides, Pindar, Thucydides and others say this in different ways. The Greek feeling about hope is vividly expressed in Anouilh's adaptation of Sophocles' *Antigone*, where, referring to herself, the heroine cries, "We are of the tribe that asks questions, and we ask them to the bitter end—until no tiniest chance of hope remains to be strangled by our hands. We are of the tribe that hates your filthy hope, your docile, female hope; hope, your whore. . . ."³

From this one can see that it was intrepid

indeed of St. Paul, writing to Greek friends, to declare that hope should stand alone, with love. In this Paul was loyal to his Hebrew heritage (Psalms 42, Isaiah 40) as well as his Christian convictions. For while the Jews were, to be sure, people of faith, they were also at all times a people of hope who, despite tribulation, clung to the expectation that the Messiah would come and the world get better. Hence, with the spread of Christianity and the dispersion of the Jews, hope had its missionaries, and Paul was one of them.

Martin Luther, like St. Paul, shook his fist at Greek fatalism and declared: "I very thing that is done in the world is done by hope." Samuel Johnson opined that "where there is no hope there can be no endeavor," and our own countryman, Emerson, took up the cudgels for hope: "it is by his hope," he said, "that we judge of a man's wisdom." "You cannot put a great hope into a small soul," said another. Jones' and Tennyson's words, "The mighty hopes that make us men," now echo in our ears.

But many poets have tended to accept (rather bitterly) the fatalistic if not cynical view of the Greeks:

Hope—fortune's cheating lottery, where for one prize a hundred blanks there be. (Cowley, 1647)

Worse than despair, worse than the bitterness of death, is hope. (Shelley: *The Genci*, 1819)

Hope is the worst of evils, for it prolongs the torment of man. (Nietzsche: *Human All-too-Human*, 1878)

I have had some patients who agreed with these poets. Partly that is why they were patients. But when I searched the literature for some kind words about hope, I experienced some uneasiness lest I find that very little (that my colleagues would accept) had ever been said for hope! And very little I found, indeed. But the cupboard proved not to be entirely bare. Particularly Dr. Thomas French, in his 5 volume examination of the psychoanalytic process, has dealt extensively with hope as the activating force of the ego's integrative function.

³ Which Creon interrupts with "Shut up! If you could see how ugly you are, shrieking those words!"

Anouilh, Jean: *Antigone and Eurydice: Two Plays*. London: Methuen, 1951.

Twenty years ago Mrs. Menninger and I submitted the thesis in *Love Against Hate* that hope was the dim awareness of unconscious wishes which, like dreams, tend to come true. We said,

There is no such thing as "idle hope." The thoughts and hopes and wishes that we entertain are already correlated to the plan of action which would bring these about, even though the whole project is ultimately renounced as too difficult or too dangerous. . . . This essential identity of hoping, wishing, purposing, intending, attempting, and doing is a little difficult for the practical common-sense man to grasp, because for him it makes a great difference whether a thing is executed or only planned or only hoped for. There is an external difference, to be sure; and there is an internal difference, too. But internally, (psychologically) from the standpoint of *motive*, there is no difference. There is a difference in the *fate* of the impulse, the degree with which it is correlated with reality, inhibited by internal fears, supported by other motives, *etc.*—but the motive force is the same. . . . The hopes we develop are therefore a measure of our maturity.

At that time it seemed to me that education best expressed the hope of the human race. But today I think I see the expression of hope in many clinical phenomena, as well.

Each of us here who has been in practice more than a decade has seen the "hopeless case" recover. And we have sometimes seen, or so it seemed, that a mother's or father's indomitable hope was a factor in this recovery. True, we have also seen hope deferred making the heart sick. But hope must be distinguished from expectation. "We are saved by hope," wrote St. Paul to some Roman Christians, "but hope that is seen is not hope: for what a man seeth, why doth he yet hope for?"

Nor is hope identical with optimism; optimism always implies some distance from reality, as Marcel points out, so that obstacles appear attenuated. The optimist, like the pessimist, emphasizes the importance of "I." But hope is humble, it is modest, it is self-less. Unconcerned with the ambiguity of past experience, hope implies process; it is an adventure, a going forward, a confident search.

When Doctors Bartemeier, Romano, Kibbie and Whitehorn and I went to the European Theatre of World War II for my brother Will and the surgeon-general, we arrived at the Buchenwald prison camp a few days after it had been entered by our armed forces. What I remember most vividly of that terrible place was something we didn't actually see. But we heard it at first hand. The night before we got there, our U. S. Army doctors had given what they called a "smoker" for the physician prisoners they had discovered and released. It was a kind of unearthly medical society meeting. Army rations were put out as refreshment, with some wine and tobacco, incredibly relished by the emaciated but overjoyed guests. Communication in words was imperfect because of language difficulties, but the spirit was unmistakable. The members of a fraternity were reunited. And in the spirit of the fraternity, experiences were exchanged.

These doctors, prisoners along with all the others, had followed the same routines of 4:00 a.m. rising, shivering roll calls, day-long drudgery on the Autobahn, shivering roll calls again, and finally a cold bowl of thin soup. They were starved and beaten and overworked like all the others, with no reason to expect any other fate than the miserable death and cremation which they observed about them daily.

But now comes the surprise. At night, when the other prisoners were asleep, these thin, hungry, weary doctors got up and huddled together in a group, and talked. They discussed cases. They organized a medical society. They prepared and presented papers. They made plans for improving health conditions. Then they began to smuggle in materials to make various medical instruments. And finally they built, of all things, an X-ray machine! The pieces had to be found somewhere; they had to be stolen, they had to be concealed in the prisoners' clothes; they had to be carried back to the prison on the long, weary marches after work. The guards had to be bribed or otherwise thrown off the scent. But little by little, with the aid of some engineers and electricians among the prisoners, these doctors put together a workable X-ray machine and used it, secretly.

at night, in their efforts to ameliorate the lot of their fellow prisoners. This was what dedication to medicine and humanity could do—**kept alive by hope.**

But, someone who remembered may ask, bitterly—what of the thousands who died miserably for *all* the hopes they nurtured? Even here I would not concede that hope had altogether failed. I would believe that hope had sustained them in their martyrdom, and that their hopefulness, however frail and tortured and ultimately defeated, was communicated on down through prison generations to those who were ultimately freed and brought us the record of this medical miracle. Who can read the eloquent last messages of the condemned as collected by Gottwitzer, Kuhn and Schneider and published as *Dying We Live*, and fail to catch a spark of hope from them?

Confirmation for the sustaining function of hope in life has recently come from a most unexpected quarter—the psychobiological laboratory. At the annual convention of the American Psychological Association in September 1956, Curt Richter of Johns Hopkins reported an astonishing phenomenon. It was simply this, that when placed in certain situations which seemed to permit of no chance for escape, even vigorous animals gave up their efforts and rapidly succumbed to death. This was observed experimentally in both laboratory rats and wild rats. "After elimination of the hopelessness feature," reported Richter, "the rats do not die . . . (Indeed, the speed of their recovery is remarkable). A rat that would quite certainly have died in another minute or two, becomes normally active and aggressive," swimming vigorously for 50 to 60 hours. Richter emphasized that not the restraint alone, nor the immersion, nor the exposure, nor the trimming of whiskers will explain the phenomenon. It is, he insisted, the loss of hope.

Richter added some confirmatory data from other fields and suggested an extrapolation from his laboratory observations to explain the occurrence of sudden death in rabbits, chimpanzees, foxes, raccoons, some birds, musk oxen, otters, mink and even human beings. "Some of these instances," he said, "can best be described in terms

of hopelessness, all avenues of escape appearing to be closed."⁴

This is not an isolated observation or hypothesis. For example, from a large amount of psychosomatic investigation Engel and his associates in Rochester, New York, consider that what they describe as "helplessness" and "hopelessness" reflect a necessary if not a sufficient condition for the development of organic disease.⁵

And then there is the Queequeg phenomena of "Voodoo Death" in Moby Dick which Walter Cannon and others have amply substantiated with authentic data from primitive societies. No doubt most of us can recall instances in which the loss of hope seemed to accelerate the arrival of death for a patient. There are many such stories, unconfirmed of course but highly suggestive, in the daily press.⁶

All of these things seem to me to support the theoretical proposal that hope reflects the working of the life instinct in

⁴ Richter, C. P.: Sudden Death Phenomenon in Animals and Humans. Unpublished Manuscript

⁵ Schmale, A. H., Jr.: Relationship of Separation and Depression to Disease (1) A Report on a Hospitalized Population Psychosomatic Medicine, July-Aug. 1958. pp. 259-277.

⁶ For example "Blasts End Mother's Will to Live," Tucson, Arizona.

Twelve days ago, Mrs. Helen F. Hopke lay in her bed fighting to stay alive to see her daughter's wedding.

Incurably ill for the past five years, Mrs. Hopke had been indirectly responsible for the meeting about a year ago of her daughter, Rose Marie, 20, and the girl's intended husband, Arthur Woodrow Hudson, 26.

Rose Marie had acted as nurse and housekeeper to her bedfast mother. While buying medicine she met Hudson, a pharmacist in a local drug store. Friends said it was the girl's first romance.

They also said all that kept Mrs. Hopke alive in recent months was the thought of the impending marriage.

The 56-year-old mother heard the couple enter the house laughing and talking about the April 4th wedding. She heard them enter the next room.

Their chatter ended in three blasts from a shotgun. Police said Hopke, opposed to the marriage, wanted his daughter to continue to care for her mother. He became enraged at reading the wedding notice in the paper, shot the couple then turned the gun on himself.

Rose Marie was taken to one hospital where she is recovering. Her mother was taken to another.

Tuesday night, Mrs. Hopke died.

(Topeka Daily Capital,
Thursday, April 2, 1959)

its constant battle against the various forces that add up to self-destruction. It would be too narrow to regard it as a form of refined narcissism since, as Marcel points out, there is something essentially unnarcissistic and beyond self in hope. One sees this in the hopefulness, not of the patient but of the physician. How much our patients do for us doctors!

We in Kansas have lived through the experience of a state hospital revival. Although we have built almost no new buildings, and although our admissions have increased tenfold in 15 years, our once overcrowded patient population has steadily diminished until we now always have available empty beds. We have even closed some wards as unneeded. We are proud of this, and proud that the voters and officials of our state appreciate it, and consider the cost per *stay* more significant than the commonly used cost per day. A distinguished governor visited us for several days, determined, as he said, to "discover the secret." "Our state has more men and more money than Kansas," he said. "Why can't we do these things?"

He didn't discover the secret partly because he didn't believe what we told him. Many of my colleagues in this audience may not believe it now, either. But we consider the crucial element in the Kansas state hospital program to have been the inculcation of hope. Not in the patients directly, but in the doctors and all those who help them, in the relatives of the patients, in the responsible officials, in the whole community, and *then* in the patients. It was not just optimism; it was not faith; it was not expectation. We had no *reason* to expect what happened, and what still happens, and our faith was only that which all scientists share. But we did have hope.

We had more than hope, you will say; we had had experiences which encouraged hope. But these experiences were themselves based partly on hope, confirming the assumption that hope fires hope. This is not a conscious process, or at least not entirely so. I have wondered if we might perhaps understand the placebo effect in this way, a transmitted hope or reinoculation, as it were? In control research studies of the new drugs, for example, patients who

receive only placebos sometimes show much improvement. In one study that I know about, testing an excellent drug, more patients in the group which had only placebos were able to be discharged from the hospital than from the group of those who got the actual remedy (although a larger number of the latter showed marked improvement).

Another phenomenon that is perhaps related to hope is the sudden improvement and even recovery of patients who have been for a long time fixed, as it were, at low levels of organization and regression. A new doctor arrives, or a new aide, and the patient promptly and most unexpectedly begins to recover.⁷

Whatever the explanation offered for such phenomena, to invoke suggestion or coincidence (whatever *they* are) will not suffice. There is more to it. And yet we doctors are so schooled against permitting ourselves to believe the intangible or impalpable or indefinite that we tend to discount the element of hope, its reviving effect as well as its survival function. Because of the vulnerability of every doctor to the temptation of playing God and taking the credit for the workings of the *vis medicatrix naturae*, we are necessarily extremely cautious in attributing change to any particular thing and least of all to our own wishful thinking.

There are many sufferers in the world, and there are many who seek to afford them relief. Among the latter there are those who use intuition and magic, and there are those who attempt to derive basic principles checked by experiment and observation, which we call the scientific method. For the former group, healing is more important than truth; for the latter, truth is more important than healing. Indeed, the search for truth, the desire to heal, and the earning of one's living are three persistently conflicting forces in medical practice.

⁷ But it is also true that just the opposite occurs: A patient on whom intensive efforts have been made fails to respond and is given up in despair, dismissed by her physician or removed to a custodial hospital. We have all frequently seen this result in a prompt improvement and even recovery. Perhaps we could regard this as an awakening of dormant hope by a desperate and unintentional shock-type method.

In the daily performance of healing acts, the scales are weighted heavily against scientific truth. Patients long to be deceived. Driven by pain and desperate with fear, they are ready to seize at "straws of hope." They prostrate themselves before the doctor; they queue up in weary, straggling lines awaiting the opportunity to submit themselves to humiliations and new sufferings, or even to hear a few words of reassurance. Beseiged by such multitudes of petitioners, often with gifts in their hands, the doctor, knowing his limitations, must try to be patient, kind and merciful—but simultaneously "objective" and honest. The desire to bring comfort, the need to earn one's living, the suppressed longing for prestige and popularity, the honest conviction of the efficacy of a pill or a program, sympathy for the pleading sufferer—all of these throw themselves upon the scales in the moment of decision. Every physician in the world has heard the devil whispering, "Command that these stones become bread . . . All these things I will give thee if thou wilt fall down and . . ." And sometimes he falls down. He exploits the patient's hope.

Against such dangers there have been for 25 centuries an oath of loyalty, a tradition of humility, and certain maxims of practice. One of the latter is the putting of diagnosis before treatment, empiricism before hope. Even in pre-scientific days it was indefensible for a doctor not to indicate some comprehension of what one claiming to be a healer was dealing with. For the patient, even a diagnosis offered *some* hope, since it showed that his condition was not unique. But for the doctor, who was better acquainted with the implications of a diagnosis for which he had no real treatment, the temptation was ever present to neglect diagnosis in the interests of hope, or at least in the interests of treatment.

It should be remembered that there were once many different kinds of competing healers. There were the apothecaries who in 1617 were granted a charter permitting them to sever their 200 year association with the grocers. There were the various trade guilds: the barber-surgeons, midwives and bone setters; and then there

were the physicians, with their plasters and clusters. All were busy "treating."

Out of this confusion, under the leadership of a gallery of immortals on pillars erected here and there over a wide area, there slowly arose the magnificent edifice of modern, scientific medicine. The elimination of superstition and magic took a century, but the purge strengthened medical science mightily. Thousands of remedies were tested, found wanting and discarded. Many improvements in diagnostic techniques and instruments were introduced. Treatment, except for the most superficial palliation, was apt to be regarded with great suspicion, while the memory of recent quackery, pretention and deceit was fresh.

In psychiatry, the efforts of our predecessors to bring order out of the apparent chaos of the phenomena of madness were reflected in assiduous efforts to describe disease entities, to name them, to identify them, to graph them, and to seek for "etiologies." This was the traditional concept of diagnosis and it offered little to justify hope. The broken or misshapen personalities coming under medical observation were described or christened with tens of thousands of names and groupings, painstakingly put together by assiduous workers, only to be discarded by those of a later generation. These old labels, like epitaphs on tombstones, may be read with sober reflections that life is short and the art long, that our grasp of human phenomena is limited and narrow, and that our concepts are ever changing and unclear.

Once diagnosis in the sense of recognizing, naming, classifying and distinguishing between different forms of behavior disorder seemed of fundamental importance. The best psychiatrist in my early days was one who could most convincingly distinguish between some of the many varieties of "paranoia" or "dementia praecox"⁸ or "psychopathic personality." Some of my colleagues "discovered" new varieties of these; I even thought that I did.

Today it seems to me most important that we *not* do that. Our impressive labels only

⁸ A term introduced 99 years ago by B. A. Morel in 1860 describing the mental condition of a boy of 14 years.

reify and freeze a phase of a process ; they misrepresent our modern concepts and they strike a blow at hope, and hence at treatment. Words like *non compos mentis* or "responsible" and "irresponsible" really indicate only whether or not we think an accused person is able to appreciate being executed. "Psychotic" and "neurotic" cannot be competently defined, since what they mean at any one moment depends upon who is using them to describe whom. Many of us have urged their abolition, but they persist as weapons in scientific name-calling. Some colleagues incline to label "psychopathic personality" all patients who admit having broken the law. And surely it is more than a little disturbing to us all to contemplate the results of the recent researches by colleagues Hollingshead and Redlich exposing the fact that what one gets called by psychiatrists depends to a degree upon what class of society one comes from.

But over and above the matter of social and political and medical misuse of terms, these diagnostic designations belie the progress we have made in understanding the nature of illness. A name is not a diagnosis. It does not determine treatment. Its original purpose, perhaps, was to distinguish between wise and foolish expectations, but its net effect has come to be that of destroying hope.

Today there is a trend away from names, states and entities and toward dynamics, relativity and process. Just as the nature of matter has assumed a new aspect, so the nature of disease has come to be understood differently. The only entities in disease, said Allbutt long ago, are the individual patients, Smith and Jones, in certain phases of their being. "Diseases are not specifics such as cats and mushrooms ; they are 'abnormal' behaviors of animals and plants." Today we are following Allbutt.

It is the privilege of some of us to be called doctors. And if the peculiar phases of existence which Jones and Smith are experiencing lead them to approach us in the belief that we can help them, they can then be called patients and their afflictions may be called disease. But we cannot discharge our responsibility by "calling." We may not exorcise Smith's afflictions by

giving them a name. That is not the basis of our hope, and if it is the basis of Smith's hope, it is one we should not exploit.

It is our responsibility as physicians to instigate some change in the relations of Smith to his environment—directly if possible, indirectly and gradually most likely. To do this we must attempt to understand the man, how he has become what he is, what goes on inside of him, what goes on around him and how these interact. By observing the internal and external processes we can discover what in his world is good for Smith and what is unbearable, what damage he inflicts upon himself and others, and what potentials within him remain underdeveloped. And here enters in hope, for we acquire, thus, a rationale for therapeutic intervention.

This is what we now call diagnosis. It were better to call it diagnosing, to indicate its transitive, continuing nature, its look toward the future rather than toward something static or past. Diagnosing is the first step in a cooperative relation between patient, physician and environment working toward the betterment of a situation, especially as it affects our patient. This is based upon hope, hope implicit in our effort and hope nurtured in our patient.

The practice of medicine today is vastly different from that of a hundred years ago when Samuel Gross wrote (1861) :

It requires no prophetic eye, no special foresight, to discover that we are on the very verge of one of the most fearful and widespread revolutions in medicine that the world has ever witnessed.⁹

That revolution came about (Dr. Earl Bond reviewed it this morning) but not so soon as Gross expected. Yet it is hard to believe today that there was ever a time when a doctor had to defend himself to his colleagues if he claimed to have cured someone. In those days hope was faint and precious. Today it seems sometimes almost as if hope was considered unnecessary.

The revolution that elevated our medical profession from a discouraged, submerged

⁹ Gross, Samuel : Quoted by Leikind, Morris C. : *The Evolution of Medical Research in the United States. In History of American Medicine.* (ed. Felix Marti-Ibanez) N. Y. : MD Publications, 1958. p. 126.

state to a progressive and confident one was partly the result of new discoveries, and partly from the recognition of psychology as one of the basic medical sciences, along with physics and chemistry. This came about from the experiences of World War I, and from the discoveries of Sigmund Freud. The latter were introduced into American psychiatry about 1920, the way prepared for them by J. J. Putnam, Ernest Southard, Adolf Meyer, William A. White, A. A. Brill and Smith Ely Jelliffe.

I cannot describe all of these old friends here, but I must say a word about Southard, because he was my teacher and because above all men I have known, and entirely out of keeping with the spirit of his day, he placed great hope in psychiatry. He said here, long ago, in 1919, *remember* :

May we not rejoice that we (psychiatrists) . . . are to be equipped by training and experience better, perhaps, than any other men to see through the apparent terrors of anarchism, of violence, of destructiveness, or paranoia—whether these tendencies are showing in capitalists or in labor leaders, in universities or in tenements, in Congress or under deserted culverts. . . . Psychiatrists must carry their analytic powers, their ingrained optimism and their tried strength of purpose not merely into the narrow circle of frank disease, but, like Seguin of old, into education; like William James, into the sphere of morals; like Isaac Ray, into jurisprudence; and above all, into economics and industry. I salute the coming years as high years for psychiatrists!

These "high years" really began after Southard died. The public had been alerted by the literary dissemination of the discoveries of Freud and also by the growing "mental hygiene movement." Most doctors had had almost no psychiatry in their medical school training. Twenty-five years after Southard had spoken those prophetic words—and died—we were in the midst of another World War. There was a shortage of psychiatrists. To enlist interest and recruit doctors, I visited medical schools over the country and talked at length to students, deans and faculty members. I found that a common objection to entering psychiatry was an impression that our patients "never get well." It is such a hopeless field,

they said. Penicillin and the other miracle drugs are more definite and exciting than the dreary wards of state hospitals, filled with silent, staring faces.

We can see, now, that these students had been shown the wrong side of psychiatry, its failures rather than its successes. But one thing struck me then which has remained in my mind indelibly. I perceived vividly how hopelessness breeds hopelessness, how the non-expectant, hope-lacking or "unimaginative" teacher can bequeath to his student a sense of impotence and futility, utterly out of keeping with facts known to both of them! Surely even these misled students knew that *some* psychiatric patients recover, even if they didn't know that the vast majority does so. But like their teachers, they adopted some of the very symptoms of their patients: hopelessness and goal-lessness! Physicians in state hospitals at that time did not expect their patients to recover, and were a little surprised when recovery occurred. Some superintendents quite unabashedly announced (published) recovery rates of 5% per year!

This experience only reinforced my conviction that hope, that neglected member of the great triad, was an indispensable factor in psychiatric treatment and psychiatric education.

At the end of the war, veterans requiring continued psychiatric treatment began returning to this country in large numbers, and at the same time the physicians who had seen these phenomena of stress and overstress develop and recede were demobilizing. Many of these doctors now sought to learn more about this psychiatry which seemed so important in understanding these cases. During the first few months of its existence, the Menninger School of Psychiatry received over 600 applications. Other training centers were similarly flooded.

Some of them no doubt came into psychiatry because of an awareness of their own threatened disorganization and the dim realization that this human-all-too-human tendency was one against which penicillin and heart surgery and all the discoveries of modern medicine offered no protection. By Freud discoveries of quite

another sort had been made and knowledge of them had slowly become common property. These discoveries promised no miracles, no instantaneous cures; they did not seem to justify hope. In fact, Freud was frequently accused of a devastating pessimism. Surely hope has rarely entered medical science through so narrow and tortuous a crevice. But it did enter and its rays transformed the face of modern psychiatry in our lifetime. A whole new viewpoint in medicine developed, one that gave authority and technique to efforts at systematic self-scrutiny, a kind of extended and continuous diagnostic case study.

In a way it seems curious that the psychoanalytic process, which is so obviously diagnostic, has generally come to be called treatment. Diagnosis is the hopeful search for a way out; but the setting forth on the way which one discovers and the unflinching persistence in making the effort—that is the treatment; that is the self-directed, self-administered change.

The psychoanalytic treatment method is a great discovery but this is not what changed psychiatry. It was the new understanding that psychoanalytic research gave us concerning men's motives and inner resources, the intensity of partially buried conflicts, the unknown and unplumbed depths and heights of our nature, the formidable power each of us holds to determine whether he lives or dies. It was the realization that we must encourage each individual to see himself not as a mere spectator of cosmic events but as a prime mover; to regard himself not as a passive incident in the infinite universe but as one important unit possessing the power to influence great decisions by making small ones.

It was not the treatment technique of psychoanalysis that changed psychiatry; it was the new understanding of men's motives and inner resources, of the intensity of partially buried conflicts, the unknown and unplumbed depths and heights of our nature, the formidable power each of us holds to determine whether he lives or dies. Wrote William James:

Will you or won't you have it so? is the most probing question we are ever asked." We are

asked it every hour of the day, and about the largest as well as the smallest, the most theoretical as well as the most practical things. We answer by *consents* or *non-consents* and not by words. What wonder that these dumb responses should seem our deepest organs of communication with the nature of things! What wonder if the effort demanded by them be the measure of our worth as men!

"Ye shall know the truth and the truth shall make you free," said another wise One. For this emancipating truth Freud searched not in physics or chemistry or biology, but in the tabooed land of the emotions. From the Pandora chest of man's mind, full of harmful and unlovely things to be released upon a protesting world, there turned up—last of all—Hope.

Selfishness, vengefulness, hate, greed, pettiness, bitterness, vindictiveness, ruthlessness, cruelty, destructiveness and even self-destructiveness—all these are in us. But not only those. Invisible at first, but slowly pervasive and neutralizing came love, and then—perhaps because of it—came faith, and then hope.

Love, faith, hope—in that order. The Greeks were wrong. Of *course* hope is real, and of course it is not evil. It is the enemy of evil, and an ally of love, which is goodness.

Freud's great courage led him to look honestly at the evil in man's nature. But he persisted in his researches to the bottom of the chest, and he discerned that potentially love is stronger than hate, that for all its core of malignancy, the nature of men can be transformed with the nurture and dispersion of love.

This was the hope that Freud's discoveries gave us. This was the spirit of the new psychiatry. It enabled us to replace therapeutic nihilism with constructive effort, to replace unsound expectations—first with hope, and then with sound expectations.

This is what it did for us, for psychiatrists. And for our patients—miserable, apprehensive, discouraged and often desperate—what can we do better than that? What can we do better than to dispel their false expectations—good and bad—and then light for them a candle of hope to show them possibilities that may become sound expectations?

And we who are teachers—can we do better by our eager, young seekers for the keys to wisdom than to help them sharpen the accuracy of their expectations without extinguishing the divine fire?

But there are many people in the world who are neither our patients nor our students, and who are nonetheless filled with great apprehensiveness, partly from ignorance and mistrust of one another. They are afflicted with great suffering which all our discoveries have not ameliorated, and awed by vast discoveries which none of us fully comprehend. Some of them look to us for

counsel, to us whom they have so highly honored and so generously rewarded with prerogatives and opportunities. They are our friends, our brothers and sisters, our neighbors, our cousins in foreign lands. For these people—for them and for ourselves—are we not now duty bound to speak up as scientists, not about a new rocket or a new fuel or a new bomb or a new gas, but about this ancient but rediscovered truth, the validity of Hope in human development,—Hope, alongside of its immortal sisters, Faith and Love.

LETTER FROM AUSTRALIA

PSYCHIATRY IN THE STATE OF VICTORIA, AUSTRALIA

Victoria, geographically, is the second smallest of the 6 Australian states; but on the other hand its population is the second highest. Although the following short account is a description of psychiatry in Victoria, it could be taken as fairly typical of psychiatry throughout Australia. There is naturally some variation between the different states, but generally speaking all appear to conform to a somewhat similar pattern.

HISTORICAL

From the year 1836 when the Colony of Victoria was founded, until 1848 at which time the first asylum was erected, lunatics were confined and cared for in the various gaols. It was not until about 1872, by which time there were 4 asylums in the Colony, that lunatic patients were finally cleared from the gaols, and all new patients were admitted directly to one or other of the asylums.

The first private asylum was established in 1868, and 5 years later the institution for the inebriates under the provision of the Inebriates Act was set up. Possibly this latter institution was the first of its kind in the world where inebriates were compelled by law to enter for treatment. The year 1887 saw the opening of a special institution for idiot and imbecile children, and the same year the criminal lunatic asylum was established.

During the first quarter of the century, two important advances were made. In 1912 there was opened a Receiving House, for admission and early treatment of certified cases, and in 1920 the Voluntary Boarder Act allowed the admission to state institutions of voluntary cases for the first time.

Evolution from custodial asylums to therapeutic mental hospitals during the first half of the century was indeed very slow and it was not until 1951, when the Mental Hygiene Authority took over the control of the state Mental Hygiene Department, replacing a one-man directorship, that any

great strides in raising the overall standard of mental hospital psychiatry were possible.

The first psychiatric outpatient clinic attached to a general hospital began to function in 1927 and several years later all 4 teaching hospitals had followed suit. By the end of the thirties the state Mental Hygiene Department had opened 4 full-time child guidance clinics.

PRESENT SITUATION OF STATE SERVICES

Today the state provides mental hygiene services for a population approaching 3 million people, and in many respects somewhat resembles the system as I saw it in the province of Ontario. This service is controlled by the Mental Hygiene Authority consisting of a Chairman and Deputy Chairman (both psychiatrists) and an Administrative lay member.

The Department consists of 3 psychiatric hospitals (early treatment), 9 mental hospitals, 4 institutions with residential schools for retarded children, 5 full-time children's clinics, 9 adult clinics conducted on a sessional basis, 3 hostels for ex-patients, 3 day hospitals and a research centre. In addition, the state subsidises some 24 special day care centres for the medium grade intellectually retarded children.

During the year 1958, new admissions to state institutions amounted to 5,878 and the average number in residence was 8,697. The total number of new outpatients seen for the year was 2,845. Treatment received in all hospitals, clinics and outpatient centres is free, and costs are met by the state.

Broadly speaking, the old hospitals are similar in design to those of the same vintage seen in parts of Canada and Great Britain. For the most part, however, these older institutions have been extensively remodelled and modernised. Together with the more modern hospitals they would appear to be superior in design and comfort to many of the mental hospitals in those two countries. Hospitals in Ontario, on the other hand, would seem to be more lavishly equipped.

During the past 8 years all hospitals here in Victoria have adopted the "open-door" policy, perhaps not to the same extent as in England but to a greater extent than was evidenced in Canada. A serious attempt is being made to carry out a full-scale program of resocialisation and rehabilitation for the long-term patient. In spite of considerable progress, we have as yet by no means reached standards anything like that existing in England, where administrative psychiatry is at a very high level.

In regard to physical treatment of psychiatric disorders, here in Australia we seem to have kept reasonably well abreast of changes and prevailing fashions in treatment overseas, but on the other hand our psychotherapeutic procedures are perhaps not as well developed as in Canada.

Psychiatric and mental deficiency nurses (male and female) receive a 3 years' training, and on qualification are registered as psychiatric and mental deficiency nurses respectively. The training program is based on the English nursing syllabus, emphasis being placed on the study of interpersonal relationships, patient management, resocialisation and rehabilitation. For senior posts and early treatment units, preference is given to those holding both psychiatric and general nursing certificates. An increasing number of general nurses are now doing a year's post-graduate study and training in psychiatry and thus qualifying in a double certificate.

The total number of medical personnel at present attached to the Department is 100, although there is an establishment for 120. Our biggest deficiency in the medical service is at the level of consultants, but it is expected that these vacancies will be gradually filled by recruitment overseas and by speeding up our own post-graduate training in psychiatry for junior officers.

In regard to ancillary staff, full use is made of psychologists, social workers, occupational therapists, and so on in clinics, but apart from a certain amount of research work, psychologists as yet are not employed in the mental hospital setting. Most hospitals have their own resident chaplains.

Victoria, as indeed most Australian states, in the past has lagged behind England and Canada in matters of research.

During recent years however research programs have been organised with the various institutions from our central Research Institute. Although still in its infancy already very useful work has been done and some very worth while contributions are now beginning to appear. This Institute has initiated an extensive program for dissemination of knowledge to both para-psychiatric organisations, public bodies, and the community.

Day hospitals here are still in the initial stages of development. Those already in existence are conducted as therapeutic centres for early treatment. In the very near future it is hoped that other centres will be operating more as day-care centres, for patients returned to the community hospital in a state of incomplete remission such as the schizophrenic and geriatric types. Day-care centres for mentally retarded children, referred to above, have been operating since 1951. These are of a high standard and receive very strong support from a large section of the community.

Over the past 20 years or so there has become a complete change in attitude of the community towards mental illness, and in fact many of the recent reforms in mental health have originated through pressure from the public. A very important organization in this field is the Mental Health Federation, which is the top-level body for all mental hospital auxiliaries and associated bodies interested in mental health. It was through the demands of the public that the Victorian Council for Mentally Retarded Children, now a very strong body, was organised with the original sole purpose of providing facilities for the care of non-institutionalised defective children.

In planning for the future, the Authority has decided that additional hospital beds are needed immediately to overcome overcrowding. In future early treatment hospitals will not exceed 100 beds and mental hospitals will be limited to a maximum of 500. During the next 10 years it is expected that 5 early treatment centres will be erected in decentralised areas to meet the local needs of these regions. Outpatient facilities are to be extended eventually to every main country general hospital and for the most

part will be staffed on a sessional basis by medical officers from the nearby psychiatric centres. A somatopathic clinic is to be opened within the next 3 months. At a later date this will be followed by the setting up of an emergency clinic and information bureau. Psychiatric services are already being provided for children's courts and penal establishments. The Department expects to take over psychiatric services in the Education and Children's Welfare Departments within the next 12 months.

REPATRIATION DEPARTMENT

Psychiatric care of the ex-serviceman is provided by the Commonwealth Repatriation Department for each state, in the way of inpatient and outpatient services. This service is on similar lines to the service for veterans in Canada.

PRIVATE PSYCHIATRIC PRACTICE

Whereas some 35 years ago there was only one private psychiatrist in the city of Melbourne, there are now no fewer than 25 engaged in private practice. The majority of private psychiatrists are attached part-time as consultants to the psychiatric units of one or other of the 6 university teaching hospitals. These units have gradually grown in strength and importance resulting in psychiatry now being accepted here as one of the major medical specialties. Although many of our psychiatrists are psychoanalytically orientated, those actively engaged in psychoanalysis still constitute a very small group.

The influence of office psychiatry was no doubt largely responsible for the acceptance of psychodynamic psychiatry in this country. To the young group of Melbourne private psychiatrists must go the credit for initiating the formation of the Australasian Association of Psychiatrists in 1946. This Association now has 180 members and 70 associate members. Full membership is restricted to those members of the profession holding an appropriate postgraduate degree or diploma, and who have been in full-time psychiatric practice for a minimum of 5 years. Annual meetings of the Association are held successively in one or other of the capital cities. Each of

the 6 states has its own branch which conducts its own affairs. The strength of the Victorian Branch at the present time is 49 members and 32 associates.

POST-GRADUATE EDUCATION

Medical postgraduates wishing to obtain the Melbourne D.P.M. are required to undergo a minimum of 2 years' training at approved mental hospitals and psychiatric units. The course given closely resembles that of the United Kingdom, the accent perhaps being at present on academic rather than on clinical training. While purely academic subjects such as psychology, psychopathology, neuroanatomy and neurophysiology, are undertaken by the respective university faculties, courses of lectures and demonstrations in psychiatry, neuropathology and neurophysiology are organised under the auspices of the permanent medical postgraduate committee and the Australasian Association of Psychiatrists. In actual practice teaching responsibilities are shared between both the private and departmental psychiatrists. The examination of D.P.M. is conducted in two parts: Part I consisting of neurology, neurophysiology and psychology 1, being taken at the end of the first year; Part II, psychiatry, neuropathology, neurology and psychopathology, at the end of the second year. The examinations have always been maintained at a very high standard as is shown by the number of successful candidates at each examination—approximately 1/3 of those sitting.

In order to raise the level of postgraduate training in Victoria, the Association of Psychiatrists is at this moment negotiating with the university authorities to have established a university department in psychiatry, and for the appointment of a professor. Incidentally, New South Wales is the only state in Australia at the present time which has such a department and a chair of psychiatry, although Queensland has had for a number of years a research professor.

Mental Hygiene
Authority, State of
Victoria, Australia.

ANALYSIS OF POPULATION REDUCTION IN NEW YORK STATE MENTAL HOSPITALS DURING THE FIRST FOUR YEARS OF LARGE-SCALE THERAPY WITH PSYCHOTROPIC DRUGS¹

HENRY BRILL, M.D., AND ROBERT E. PATTON²

INTRODUCTION AND BACKGROUND DATA

On June 30, 1955 the resident population of New York State's mental hospitals had reached an all time high of 95,000. The previous year had brought an increase of 2,400 (Fig. 1); this was the continuation of a long-term trend that had doubled the mental hospital cases since 1920. Many factors had changed during that time; the population of the state had increased, the proportion of aged had grown; mortality in the hospitals had been diminished, and mental hospitals were being used more, annual first admissions for all types of psychoses had risen from 72 per 100,000 in 1930 to 103 in 1955. These explained the situation in part at least but the fact remained that the sheer speed of growth represented a problem in itself and there was no indication of a slackening of pace. Overcrowding had reached an overall figure of 334(1) and the existing shortage of 23,000 beds seemed destined to be increased each year by another 2,000 or more cases. At that time there was little comfort in the fact that the highest point in first admissions had been reached in 1950 and had not risen further, or that significant advances had been taking place in psychiatric treatment.

In 1955-56 this upward trend was abruptly reversed and converted into a fall of 500 for the year (Fig. 1). In itself, this was a small change but it gained significance from several associated circumstances: 1. The speed and consistency of the previous rise. 2. The fact that similar decreases were reported quite widely from other mental hospitals, both in this country and abroad. 3. It was coincidental with the introduction of a new form of psychiatric therapy, that of the tranquilizing drugs. In New York State this method of treatment

was first used on a large scale in 1955 when 30,000 cases received drug treatment.

Analyzing the New York experience, the authors² came to the conclusion that the abrupt population fall was in material degree due to the introduction of the new drugs. The method used was to contrast the overall statistical and administrative data for the first year of large scale drug therapy with the data for the year immediately preceding. No other explanation for the statistical changes could be found and the distribution of the effect was such that it seemed to reflect the action of the drugs, being greatest in those types of cases where their advantage over previous methods was clinically highest and least marked or absent in other types, such as organic states.

From the first, the favorable turn in mental hospital figures had attracted wide attention and had a more profound and immediate effect on general opinion with regard to hospital maintenance and construction than might be judged from printed reports. In some quarters the small changes were promptly projected with quick optimism and there were reports that in several parts of the world building programs were held up in expectation of some overwhelming change which would empty the hospitals. Forgotten was the argument that the mental hospital problem was created by the mental hospital and for that reason it could be solved only by building no more hospitals or abolishing those which did exist. A contradictory line of logic served to reach the same conclusion. The reasoning now was that due to drug therapy the problem was no longer with us and that the hospitals could be abandoned. Actually, we had had only a small and brief though promising experience. Many questions remain unanswered—some of them quite decisive—for example, "How stable and how extensive would the change prove to be?" The answer was of more than academic interest. If, as some

¹ Read at the 115th annual meeting of The American Psychiatric Association, Philadelphia, Pa., Apr. 27-May 1, 1959.

² Department of Mental Hygiene, State of New York, Albany, N. Y.

FIG. 1

ANNUAL INCREASE IN RESIDENT PATIENTS

claimed, this was the beginning of a far-reaching decrease, building programs might well be abandoned and the problem of mental hospital psychiatry could be considered solved except for the small amount of time required to complete the transition. On the other hand, many felt that the change was coincidental or that drug effects merely masked the symptoms of mental disorder for a time and produced a type of spurious superficial improvement which would soon be unmasked with a return to the hospital for individual cases and, in the aggregate, a reversion to the previous type of hospital statistics. According to this view, the use of tranquilizers was a regrettable but transitory fad.

Only time could resolve such questions; several years of additional experience have now accumulated. It is already quite ob-

vious that regardless of theoretical considerations drug therapy on a large scale is more than a transitory fad in mental hospital practice. It also is becoming clear that whatever the causes of the original shift in the hospital statistics they represent more than a brief cyclical reversal of an old trend; we are faced with a phenomenon that does not have any precedent and data bearing on this important topic are worth analysis and review since the interpretation of the changes which have taken place is still a matter of active controversy and important practical decisions of positive and negative nature hang on such interpretations.

METHOD AND ASSUMPTIONS

In New York the fall in population has continued for 4 consecutive years and sta-

istical data for the first 3 of these years are now available for study. It will be the purpose of this paper to analyze the overall figures to try to identify those classes and kinds of patients most, and those least, affected, and to trace some tendencies which seem to have implications for the future, seeking at least partial answers to some of the questions mentioned above. The method, similar to that outlined in our first report(2) will not be further described here except to say that it represents an analysis of the total work of the institutions during one period compared with the total results at another. The assumption is that such total comparisons may reveal the operation of factors which might be less certainly recognized when smaller numbers are used. Particularly a measure of the change in the total therapeutic potential of the mental hospital system is being sought. Such a comparison is facilitated when the two periods are closely spaced so that as few conditions may change as possible. As time goes on, there is more opportunity for other known and unknown factors to be introduced; to a certain extent this has already taken place in our series, and this will be described below.

The measure of therapeutic potential has been the capacity to return patients to society. It is recognized that return to the community does not represent an end in itself and can be easily subject to changes of administrative policy. We can only say that such policy changes have not taken place. Moreover, anyone who has attempted to change the operating conditions of a large organization knows the inherent difficulties and will recognize that sweeping administrative changes are virtually impossible to achieve quickly, but require a period of years. The fact is that no effort was made to produce any administrative changes during the first year of large-scale drug therapy; during the last 3, a very active program of change and liberalization has been under way. We can now go on to examine the specific statistical changes comparing 3 successive periods:

1. The year 1954-55 when no drug therapy was in use.

2. The year 1955-56 when large-scale drug therapy was introduced.

3. The years 1956-58 when a number of other favorable factors were added.

VOLUME OF DRUG THERAPY

From the start there has been a steady increase in the volume of drug therapy (Fig 2). Since all treatment is at the initiative of the treating physician, and the medical staff of the Department numbers about 900, this reflects a relatively broad professional judgment, sustained incidentally by firm opinion among ward personnel of various grades. The number now under treatment is over 45,000 (including 3,800 in the state schools) and the budget for psychiatric drugs is \$2,200,000 per year. Chlorpromazine still accounts for the largest share with 26,000 cases and reserpine is next with 3,700 but a steadily increasing number of other substances, mostly phenothiazines, are coming into use.

What seems to be an undue decrease in the use of other methods of somatic therapy has been noted. For example, less than a thousand cases are listed as receiving electric shock therapy as compared with 4,000 in 1954, and psychosurgery has been all but abandoned, yet most observers agree that these treatments still have a place in the therapeutic armamentarium.

The proportion of cases under therapy with all forms of somatic therapy is greatest among the newly admitted at 68% (Table 3) and least among cases of over 10 years with 19%; it falls rapidly after the 1-4 year group where it still reaches 42% of the cases. It is interesting to note that drugs are most used in those classes of patients which have shown the greatest response in absolute numbers; improvement relative to previous results has less weight. The authors are of the opinion that experience with favorable response encourages more treatment of similar cases and failures have the opposite effect. When we turn to diagnosis as a guide to choice of therapy, we find much less specificity, and the percentage considered suitable for treatment shows surprisingly little variation from the general 30% average.

FIG. 2

SPECIAL THERAPY, RESTRAINT-SECLUSION AND RESIDENT PATIENTS

BEHAVIOR EFFECT

Reduction in the use of restraint and seclusion was one of the earliest overall effects of the new drugs, and the one which has been most consistent (Fig. 2). This was rapid at first but has now apparently reached a plateau value at one-eighth the original level. In spite of early fears, the drugs did not "wear off" although there has been a rather general tendency to try new products as they appear and each of these seems to find patients who respond particularly well to them. A variable preference among physicians for one or another drug is

also to be noted and this is taken to mean that the differences among many of the agents is not a decisive one.

POPULATION FALL (OVERALL)

The overall effect of drugs on the population had the same sequence as that seen on individual cases (Fig. 2). A behavior response was already measurable very early during the limited experimental use of chlorpromazine and reserpine in 1954 and was quite well marked early in 1955. Release effects came much more slowly after months of large-scale use; by the end of the first year this was clear.

TABLE 3

PATIENT TREATMENTS IN NEW YORK CIVIL STATE MENTAL HOSPITALS BY TIME SINCE ADMISSION OF PATIENTS TREATED, FISCAL YEAR ENDED MARCH 31, 1958

Per cent of Patients available treated	31%	68%	42%	23%	19%	1%

A CAUSE AND EFFECT RELATION

The establishment of a cause-effect relation between drug use and fall in population was difficult for the first year but we could report that there was no important change of general operating conditions or of policy, and this left the drug effect as the most simple and direct explanation, supported by internal evidence (distribution of improvement in releases). The situation is more complex for the last 3 years of this program. In 1956 the Department began a new program of intensified treatment for newly admitted patients which has gradually been extended to all the institutions. In addition, a sweeping program of liberalization of hospital operations began to be felt in the second year and has gone on to full development in the last two years. A part of it, the "open hospital" system, brought freedom of the grounds to some 60% of all cases by March 1959, fully 10 times the figure recorded in 1956.

Without the first year's study, it would now be indeed difficult to identify the effect of drug therapy among the various new influences on the patient population. However, when compared with the first year's results it becomes apparent that the effect of the additional resources has been to intensify the results already noted in the first year but not to change their pattern materially. It also seems certain that the drug effect facilitated the liberalization of

hospital policy and it is generally accepted among our staffs that it would be quite impossible to operate as we now do without the use of drug therapy in liberal quantities. Another change of the new and liberalized regime has been the increased number of admissions by voluntary and semi-voluntary procedures from 1,770 in 1955 to 5,910 in 1958. This has led to an increase in the number of direct discharges and may in the future lead to a larger number of short-term cases.

One of the most important changes, however, remains the fact that the 15 mental hospitals described in this paper are now serving the total mental hospital needs of the growing population of New York State with 4,100 beds less than they needed 4 years ago and apparently the need is still decreasing. It is important to know what types of cases are decreasing and how is this improvement distributed through the hospital population? Is there any evidence as to the stability of this change? Are we dealing with a process which returns patients more rapidly to the community only to get them back into the hospital more rapidly? Is there a tendency to release the patients for a year or so and then receive them back as readmissions? The size of the population of a hospital is the result of a balance between additions and removals, and among the removals are deaths as well as discharges and other releases.

TABLE 1

MOVEMENT OF RESIDENT PATIENTS IN NEW YORK CIVIL STATE MENTAL HOSPITALS
FISCAL YEARS ENDING MARCH 31, 1955 THROUGH MARCH 31, 1959

<i>Fiscal year ended on March 31</i>	<i>Resident patients start of period</i>	<i>Admissions</i>	<i>Deaths</i>	<i>All released alive</i>	<i>All returns</i>	<i>Resident patients end of period</i>	<i>Change in Resident Patients</i>
1955	90,893	21,459	8,078	16,069	5,109	93,314	+ 2,421
1956	93,314	21,454	8,345	18,562	5,301	92,862	-452
1957	92,862	21,828	8,555	19,785	6,059	92,409	-453
1958	92,409	23,266	9,421	21,733	6,650	91,191	-1,218
1959	91,191	25,254	9,197	25,607	7,562	89,203	-1,988

What has happened to the other components of the equation?

STABILITY OF RESPONSE (IMMEDIATE)

It remained to be seen after the first year of success whether the results in terms of overall hospital figures would prove permanent. There were many who postulated that the effect on an individual patient was merely to mask the symptoms for a time, that the disease process went on relentlessly and would soon bring the patient back to the institutions in as bad a condition as if he had never had this brief reprieve. Even a brief reprieve would have been welcome but the overall figures up to the present time do not give any indication that we are dealing with an essentially temporary effect. Clinically, it has proved practical to carry an estimated 50% of cases for a time on maintenance drug therapy after leaving the hospital and this has undoubtedly stabilized the results. Now it can be said that the patients who are released under therapy with drugs show a somewhat smaller return rate than the non-treated cases in the first year after release. This may be a result of selection of cases since during the year 1954-55, 13,992 were placed on convalescent care and 5,104 were returned, or a total of 35%, and this percentage of returns has remained essentially constant since. In other words, a sharply increased number of patients released proved to be as stable in their adjustment measured by return figures as a smaller number previously released. Judged by this criterion, it would seem that the grade of cases released was not different from that previously obtaining; the number

of cases released is a function of the release criteria of the hospital but the number of cases returned is a function of social tolerance. We have no reason to believe that the social tolerance has increased in New York State during the last 4 years.

LONG-TERM STABILITY

A delayed instability of therapeutic result would be reflected in a rising proportion of readmissions; in fact, however, the proportion of readmissions has not risen. Tracing the relation between the two figures back to 1952, we find that readmissions have steadily made up almost exactly 27% of all admissions and this has remained so during the 3 years of large-scale drug therapy for which figures are available. It may be expected that this percentage will be increased, however, as the new and liberalized policy of voluntary admission begins to take effect since releases after such admissions usually result in administrative discharge, and more of the returning cases will probably be listed technically as readmissions and less as "returns from convalescent status," now usually maintained for about a year.

It is generally thought that socioeconomic factors have an important influence on the admission and release of mental hospital patients. From this point of view, it is interesting to note that there was no unfavorable effect from the economic recession of 1958. Population reduction continued during that year of depressed economy and increased unemployment although we had expected that an economic change might well reverse the trend.

TABLE 4

RELEASE FROM AND RETURN TO ALL NEW YORK CIVIL STATE MENTAL HOSPITALS BY TREATMENT STATUS, FISCAL YEAR ENDING, MARCH 31, 1958

	Males		Females	
	Treated with Tranquilizing Drugs	Not Treated	Treated with Tranquilizing Drugs	Not Treated
Population at risk ^a	21,433	25,906	35,294	23,433
Release Alive Rate ^b	21.3	11.1	19.3	9.5
Return Percentage ^c	39%	48%	35%	45%

^a Resident Patients 3/31/57 plus admissions during year.^b Includes releases on convalescent care, family care and escape per 100 at risk.^c Includes returns from all above statuses per 100 released alive.**DIFFERENTIAL EFFECT OF THE NEW TREND WITH REGARD TO MALE AND FEMALE CASES**

The population fall of the last 3 years has been 506 for men and 1,617 for women. It was noted that 21,433 male and 35,294 female cases received therapy (Table 4), that is, 60% of the women and only 43% of the men were considered suitable for therapy with drugs. This difference is noted in each of the age groups and in each diagnostic group and also when patients are divided according to duration of hospital stay. Nevertheless, the release rate for treated males is slightly higher than that for females, and the same is true of the rates for untreated male and female cases although releases among treated cases are twice those of untreated cases. It is an important question why a smaller proportion of male cases is considered treatable by drugs and by practically all other methods.

DEATHS

It will be noted in Table I that in 1958 there were 9,421 deaths in hospitals and that this represents a considerable increase over the 1957 figure of 8,555. Some of this is due to a trend toward aging of the population (Fig. 3) but it is in large part due to the recent epidemic of Asian influenza. Because of concern about possible late morbidity and mortality after drug therapy, we have been observing mortality statistics as a possible lead to any long-term effects not detectable clinically. It will be

seen (Table 5) that the age specific mortality figures are far below those of 1929-31, and the rates of 1955-57 were not raised by the introduction of drug therapy. The year 1958 shows an increase, however, in all but one age group and this result of the influenza may also be expected to be reflected in the 1959 statistics. The effect of drug therapy in reducing immediate mortality due to psychotic behavior is clearly seen in Table 6.

A certain amount of the most recent fall in population is to be attributed to the excess death rate in 1958 and 1959 but effect of this is of a transitory nature because 1,209 of the 1,343 increase of deaths since 1955 were in the over 65 group and 113 in the 55-64 group. Below the age of 54 the increase was 21 cases, yet the population effect with which we are most concerned is in the younger groups (Fig. 3).

Clinically it has not been possible to identify any evidence that there is any morbidity associated with long-term use of drug therapy, nor has this appeared in any of the reports of the state hospital pathology departments carrying on routine post-mortem studies. Another fact of interest is that although a certain number of cases develop depressions in the course of therapy with the phenothiazines the number of suicides reported from the mental hospitals has remained consistently below the average for the preceding 10 years although the variations in the totals are too small to be statistically significant.

WITHIN 6 MONTHS OF ADMISSION AS A PER CENT OF ALL ADMISSIONS, BY AGE

Fiscal year ended on March 31	All Ages	Age (Years)					
		Less than 25	25-34	35-44	45-64	65-74	75 and over
1955	13.0	0.4	0.8	1.4	7.7	26.5	43.0
1956	12.4	0.3	0.6	1.1	6.8	24.6	41.5
1957	12.1	0.1	0.8	1.0	6.4	24.9	40.3

EFFECT ON AGE DISTRIBUTION

The emphasis on the increase of aged cases in the mental hospitals and the practical problems of preparing to care for a steadily increasing proportion of such individuals makes it important to notice how the population reduction is distributed as to age. It will be noted (Fig. 3) that between 1949 and 1955 all age groups increased although the largest increase was in the group over 65. The fall which has

now taken place has been most marked in the 25-44 category, which was reduced by 3,368, while the group aged 45-64 decreased 967. A rise in the over 65 cases and in the under 25 group continued, leaving an overall decrease of 2,123 for the 3 years analyzed. It should be noted that the ranks of the 65 and over are augmented by aging within the hospital cases by some 1,800 each year. This aging is an expression of the chronicity of mental disease and ac-

FIG. 4

RESIDENT PATIENTS BY MENTAL DISORDER

counts for fully half of all the over 65 cases. The reduction of population among the younger age groups apparent in Fig. 3 is one of the most hopeful elements in our data but a reservoir of chronic younger cases still remains and it is still being augmented by therapeutic failures.

REDUCTION BY DIAGNOSIS

Comparing the hospital population of March 31, 1955 with that of March 31, 1958 (Fig. 4) after 3 full years of large-scale drug therapy, we find that there has been an overall reduction of 2,123 with a fall of

2,112 in the schizophrenic group, 395 in the affective psychoses and 420 in a mixed group including psychoneuroses, paresis, organic states of various types, *etc.* These were counter-balanced by an increase of 511 in character disorders, 267 alcoholics and 26 in the senium.

Within the group of schizophrenics (Fig. 5), the 25-44 age group showed a 3-year reduction of 2,979, the 45-64 year group showed a fall of 183 and there was an increase in the under 25 and the over 65, the first from a marked increase in admissions under age 16 and the latter as a

FIG. 5

RESIDENT PATIENTS WITH SCHIZOPHRENIA, BY AGE

result of receiving additions from hospital cases of long residence.

When we examine the schizophrenic group for duration of hospital residence (Fig. 6), the problem of chronicity appears in startling clearness. At one end of the scale is the 10 years plus group numbering over 31,000 and, in spite of advances in therapy, their number has actually increased by 527 in the last 3 years. The reservoirs from which this very chronic group are augmented have shown a clear-cut change. The 5-9 year class has ceased to grow, while the 2-4 year group has fallen by 1,463, and the schizophrenic cases in their second year of hospital life have diminished by 27%. The cases of the current year have diminished by less than 8%. Since the figures for the current year are a crude measure of speed of therapy, it would seem that we may have gained less in speed of therapy than in effectiveness in prevention of chronicity. A marked cut

in the second, third and fourth-year cases must in the long-term cut total chronicity very significantly. However, the problem of chronic schizophrenia will never be gone until its feed lines are cut off and we have no indications that we have done more than reduced them as yet. If we reduce the size of these sources by a quarter or a third, we may expect that much reduction of final chronicity but not more. Then, depending on such counterbalancing factors as (a) further extension of length of life; (b) continued increase of total population of the state; and (c) increase of other types of psychiatry, we may come to a new equilibrium which will require some further technical advance before it can be broken.

A glance at Fig. 6 will show that there are some 50,000 cases other than chronic schizophrenics in the New York State mental hospitals and even if the chronic schizophrenics were to be entirely eliminated, which appears to be unlikely from the

FIG. 6

RESIDENT PATIENTS WITH SCHIZOPHRENIA, BY TIME SINCE ADMISSION

above data, there will be need for extensive facilities for these other cases, most of whom belong to categories where modern therapeutic advances have made relatively little impression.

SUMMARY

In 1955 the New York State mental hospitals undertook a large-scale program of tranquilizing drug therapy which during

the first full year of its operation reached 27.9% of all cases(2). This was a 250% increase of use of somatic therapy in one year and was followed by a reduction of 500 in patient population, reversing a long-term increase of some 2,000 per year. The data for that year were analyzed and were compared with that of the year preceding when the population had increased by 2,500 and the conclusion reached that the addi-

tion of drug therapy was the only significant identifiable change which had occurred in the treatment conditions of the Department and that the favorable change was attributable in major degree to the use of chlorpromazine and reserpine.

Another 3 years have now passed and the fall has continued. The population on March 31, 1959 was 4,100 below the figure of 4 years before and this apparently represents a well-marked trend. It is, however, no longer possible to say that circumstances have remained essentially the same as they were before the use of drug therapy was undertaken; a whole series of progressive changes have occurred; a sweeping program of liberalization of hospital policy has developed; open hospital techniques, encouragement of admissions other than by judicial certification and the organization of a number of experimental programs have been undertaken. Intensification of treatment for newly admitted patients has been secured through assignment of additional personnel for admission services and special geriatric and continued treatment programs have also been set up. In spite of this, the pattern of change has not deviated significantly from that already identified when drug therapy was the only new modality. A significant increase of amount of change has, however, taken place but it becomes quite impossible to assign a quantitative role to each factor; what seems certain is that all these elements are mutually interdependent and reinforce each other. It now becomes important to analyze the trends for their significance with regard to future plans for mental hospitals, especially as many mental hospitals in various parts of the world have noted a decreased pressure for hospital beds or an outright fall in population. In some quarters these changes have been discounted as cyclical and unimportant and in others the attitude has been that it is now a matter of a relatively short time before mental hospitals will be empty and that the problem of hospital psychiatry has at long last been solved.

Our own data lead us to take a position somewhat between these two extremes and considerably toward the conservative side. The persistence of reduction for 4 succes-

sive years seems to rule out any cyclical variation and the fact that the reduction of population is limited to functional cases and most marked in schizophrenics points to the action of a specific therapeutic influence rather than a general change of policy. In New York during the last 5 years the number of cases actively carried on somatic therapy at all times has jumped from 4,000 to over 40,000, the number released from hospitals has gone from 14,362 in 1955 to 19,334 in 1958, and, in addition, the atmosphere of the state mental hospitals has been virtually revolutionized. Restraint and seclusion have been reduced to an eighth of their previous level and a series of liberal policies has been facilitated beyond what might have been dreamed of on such a scale 5 years ago.

However important these changes may be from the point of view of the mental hospital as a therapeutic organization, there are other facts which tend to support a more conservative attitude with regard to the extent that the present change may be projected into the future, and especially the projection of any factor of acceleration in the present process.

Although there has been a 34% increase in patient releases in New York State during the first 3 years of drug use, admissions were up about 12% and information from other hospital systems here and abroad indicates that this is a general phenomenon. The number of schizophrenic patients released has increased 39% during the 3 years for which data are available and the release percentage of chronic cases of up to 10 years' hospital residence has been increased strikingly, yet a simple review of the present mental hospital population indicates that there still are a considerable number of cases on the way to becoming chronic hospital residents; the number of 2-4 year cases, for instance, has been reduced by 27% but this gives secure promise to reduce the eventual permanently chronic group by this amount. Furthermore, mental hospital operations involve far more than schizophrenics. There are many other categories of cases and in our hospitals these have either remained stationary in numbers or have continued a long-term increase.

Finally, there is a small but very signifi-

cant group of cases, especially in the age group below 16, which have been coming rapidly to the fore in the past few years. Numbering less than 400 in 1950, these now are being admitted at the rate of 700 to 800 per year, and that figure would be higher if our facilities were more adequate. These cases must have more than double the hospital space of adults and much more personal service. Those who fail in therapy may look forward to a long life in hospital or a long career of behavior disorder in the community. Some feel that these should be elsewhere than in a mental hospital but society seems to have decided otherwise and we have been for several years subjected to unrelenting pressure for their care and treatment, and whatever else one may say it must be admitted that the problem is a psychiatric one.

Another group which warrants comment is the so-called character disorders. Patients in this group increased from 1,293 in 1955 to 1,804 in 1958. To a large extent this group overlaps the teen-age problem just described but some of them are adults. Although here, too, the battle rages as to the proper function of a state hospital, the result is still to send a larger group for such care. In the main, they, too, represent a type of psychiatric problem, although this is far from saying that every case of acting-out is properly classified in a mental hospital. What we are discussing here is the fact that an increasing proportion of such cases actually are coming to us and must be considered in our plans. Still in the same category are the alcoholics whose number increased somewhat in the last few years from 3,693 to 3,960. In the past, the mental hospitals have made but a limited contribution in this field, taking an almost neutral attitude in the rehabilitation of such individuals. This was justified only so long as we could do no better. As our facilities improve, a greater interest must be taken in this disorder. Alcoholism has long been identified as a psychiatric problem and whatever treatment has been available has tended to be in mental hospitals. It is inevitable that we shall be called upon to take a more positive role in this situation which is said to involve some 3,000,000 Americans. Up to the present, much of this

has been forced into the category of a sort of "deferred business" due to sheer lack of facilities. It seems inevitable that as soon as any space becomes available this question will be moved for a more satisfactory disposition. If we look only at the reduction in our population, we may forecast a rather gradual melting away of the chronic schizophrenic cases to perhaps 50 to 75% of their present number which is a humane and practical advance that would relieve New York State of a quarter of its present mental hospital population. Statistical data and clinical experience indicate that the reduction will be more rapid on the women's services than on the male side where fewer cases are found for therapy. For some time to come the number of long-term schizophrenic cases who pass their old age in the mental hospitals will continue to increase and will continue to leave the impression that the hospitals have been overwhelmed with geriatric admissions.

DIVERSIFICATION OF PRACTICE

Thus, while population reduction is a clear-cut fact and promises much for the future, if we look at the whole question more broadly we may see a somewhat different picture; if the mental hospitals are to meet the demands of society, they will have to continue to diversify their practice even beyond what has already been done. This will involve a continually larger admission rate, a more rapid turnover of cases, and the development of psychiatric care for a wide variety of conditions which at present are received in our hospitals but accorded relatively little attention. Society has many unmet needs in this area, and the mental hospitals have a responsibility here. It does appear that within the next few years some beds will become available at least in geographical areas which have already been able to keep up with previous needs to a reasonable degree. At the present time the New York statistics and the New York experience indicate that the unmet needs may outrun the prospects of new available mental hospital space, failing some revolutionary therapeutic advances. Yet it must be remembered that New York State now has some 580 mental hospital beds for each 100,000 of its general pop-

ulation. What the sequence of events may be in localities which have far less available space is not clear from our experience. Many factors, such as degree of urbanization, use of alternative facilities, especially for the aged, and local attitudes, must play an important role in determining what will be the need of psychiatric beds in any area, but it would seem that a very con-

servative attitude is justified. So far we have not heard of a single instance where psychiatric beds were no longer able to be utilized.

* Exposures—resident patients plus $\frac{1}{2}$ the deaths during the period.

** Standardized based on the age distribution of 1955 exposures.

DISCUSSION

JOSEPH BARRETT, M.D. (Williamsburg, Va.)—Any program that can reduce the population of a hospital system to the extent reported here must be quite gratifying. The fact that the 18 hospitals described in this paper are now serving the total mental hospital needs of the growing population of New York State with 4,100 beds less than they needed 4 years ago justifies the program. Percentagewise this is a 4.4% drop or 1.1% annually.

It seems to me that there may be a number of factors which make this great migration out of the hospitals possible—something other than the ataractic drugs.

First, there has been a decided improvement in the numbers of medical and nursing personnel. The need for this personnel was hard to sell on the basis of better care and increased psychotherapy, etc., but the general public can actually buy this additional personnel for the purpose of administering drugs, etc. This has led to more individual attention to patients, which in essence is an improved or increased total push program.

Second, there has been a change in attitude not only on the part of the family but also on the part of neighbors toward a mentally sick person returning to their midst. Here is a person who has actually been treated, a form of treatment they can understand. The patient's chemistry has been changed. The entire community has a more favorable attitude toward the mentally ill patient and we have found that not only previous employers but also new employers have a more favorable attitude toward a successfully treated mental patient.

Third, I think there has been a very definite change in attitude on the part of the general practitioner in the community. Here is a form of treatment he can actively participate in not only by contributing to the continuation of medication and observation of the results, but we see numbers of cases coming to the hospitals which the family doctor has tried to prevent by inadequate medication.

I have recently had correspondence from a family physician wanting to know how we were able to send home at the end of 3 weeks treatment a patient he had sent in

for long term care. So there has been much help from the outside as well as the push from the inside.

We have been having very similar experiences in Virginia to those reported by Dr. Brill in New York. We have found it most helpful to patients remaining out of the hospital if the medication and hospital supervision, through the work of a social service department, can be maintained for sometime. To this end we have follow-up clinics, which I am sure Dr. Brill has too, and here we meet additional problems. In the matter of medication we find that many patients are unable to provide the cost. When we talk about supplying it at hospital or public expense we run into a type of socialized medicine response. The value of follow up clinics is frequently questioned and we are presently making a detailed research study of 3 such clinics in the Eastern State Hospital area and will report this study when completed, but from my June 30, 1958 Annual Report the following quote is very significant:

"It is interesting to note that of the 1,604 patients released from the hospital during the year, 866 or 59% of these patients returned to the hospital. Of the 414 furloughed patients followed in clinics only 122 or 29% returned."

The seeming increase in mortality under drug therapy may well be due to masking of physical symptoms (such as nausea, vomiting, etc. and even fevers) and suggests a need for continued and increased alert medical personnel.

Volume of Drug Therapy in Virginia:

During the year ending June 30, 1958 in the Virginia hospitals we had a total of 15,385 patients under drug treatment. This is an increase of 5,800 over the previous year. We still use much shock therapy, but on a reduced scale.

Stability of Response:

I do believe that the degree of stability derived from the various drugs must be attributed to many other factors such as attitudes, concepts and general willingness to accept what appears to be permanent damage in some types of mental disorders, and the ability of the hospital or clinic to proffer continued guidance.

CHILDREN AND ADOLESCENTS WHO HAVE KILLED¹

LAURETTA BENDER, M.D.²

Since 1935 the author has personally known 33 boys and girls who, before they were 16 years of age, had been associated with the death of another person either by causing or being blamed for a death by themselves or others. All of these boys and girls have been examined, many of them repeatedly, in public institutions of New York.

This present brief study will analyze the significant data concerning this group of 33 individuals in terms of their background, the incident that resulted in death to the victim, any specific clinical pathology, the reaction of the young person involved and his or her subsequent career. There will be no effort to discuss individual cases or elaborate on psychodynamics. This has been done before for some of these cases (1, 2, 3). Longitudinal or followup studies have also been published (4) which have been further extended for the present study.

There were only 2 girls in the series. They were 5 and 8 years of age when each accidentally ignited the clothes of a younger sister leading to death within a few hours. The 31 boys were 5-15 years of age at the time of the fatal incident in which they were involved. Six were 5 and 6 years, 5 were 7 to 10 years, 9 were 11 and 12 years, and 11 were 13 to 15 years. Thus, 13 children were under 11 years or prepuberty and 20 boys were 11 to 15 years of age.

There were 11 Protestants of whom 9 were Negroes and 17 Catholics including 2 Puerto Ricans.

Intellectually, 2 were grossly retarded, 5 were borderline defective, 20 were in the normal range with IQ's recorded from 80 to 110, 6 had higher IQ's. Eight of the boys were non-readers (including the two grossly defective), 9 were retarded readers, 9

attained average reading skill and 4 were superior readers.

Before considering the clinical data it will be well to emphasize that the 33 boys and girls can be readily considered in two nearly equal groups. Sixteen were involved with the fatal incident and known to the author between 1935 and 1944 or the first 10 years of this study. They are now 20 to 40 years of age. This group is characterized by the lack of more recent intensive methods of clinical study and diagnostic evaluations and by their adulthood and followup studies that indicate the course of their life patterns. Seven are in high security institutions. None was considered schizophrenic at the time of the fatal incidents, although several were considered defective or brain damaged. However, 5 have been diagnosed as schizophrenic and psychotic subsequently. Two are known to be doing well, including a girl, in spite of very bad home circumstances. Three are presumed to be doing well, having been placed in adequate foster care and further difficulties are not reported. The remaining four, after a considerable period of training school or hospital care, are maintaining a precarious status in the community.

Seventeen were involved in the fatal incident in the last 10 years since 1948 and are currently 8 to 22 years of age (10 are still under 16 years). This group have been subjects of intensive clinical studies and most of them are still under treatment in New York State hospitals or training schools immediately available to the author (5 are currently in the children's unit of the Creedmoor State Hospital). Five are in the community under careful supervision, two others have been out but further trouble led to higher security institutionalization. It is in this younger group that a great deal of severe pathology was uncovered which will be described.

Next, let us consider a classification by mode of death.

1. Death was caused by fires set by 6

¹ Read at the 115th annual meeting of The American Psychiatric Association, Philadelphia, Pa., Apr. 27-May 1, 1959.

² New York State Department of Mental Hygiene, Creedmoor State Hospital, Children's Unit, Queens Village, N. Y.

children, including the two girls. Their ages were 5 years (two), 6, 8 and 12 years (two boys). These were all evidently unintentional deaths. However, like the serious fire-setters described by Helen Yarnell (5, 6) they all had very disturbing home situations. One was grossly defective and his two defective younger brothers perished in the fire, set by the three while they were left alone. Two of these children now under hospital care are schizophrenic. The other three, belonging to the older age group, have made satisfactory adjustments, two to foster care. All of these children showed the severe depressive, guilt-ridden grief reaction previously described (1). There was no record of these children setting fires subsequently. On the other hand, among the 27 children who caused death by some other means than fire, there were 8 who were compulsive fire-setters, including all 5 who were associated with a death by drowning.

2. Death by drowning was associated with 5 children, ages 5, 9, 10 (two boys) and 11 years. Because of the nature of this type death, in none of these instances was it ever known whether the child implicated was guilty of any intentional act either of omission or commission. In one case of a 10-year-old boy, he and his friend were having a friendly wrestle on the river bank and his friend fell in and could not be saved. This boy had the most violent reactive psychotic depression with a phobia against water even for washing, bathing or drinking for some time. Like the others in this series he also had nightly dreams of drowning himself or other people or of sea monsters after him or of submarine disasters. These boys all required months or years of hospital care for their reactive depression. Two were put on convalescent care but after aggressive crimes were placed in corrective institutions. All were fire-setters. All have threatened to kill. Three have been diagnosed as schizophrenia. One was associated with the death of two children at some months' interval.

3. Three younger children were associated with deaths not readily classified. A 5-year-old blind defective boy with retrolental fibroplasia following premature

birth choked his 4-week-old sister to death when he was bothered by her crying. He also threatened to repeat this on other crying children. He is hospitalized. A 5-year-old boy considered retarded and showing an impulse disorder following an infectious encephalitis, was accused of pushing his 3-year-old brother out the window. Now at the age of 23 he is hospitalized as a psychotic schizophrenic. A 7-year-old boy, long recognized as a problem, mildly microcephalic, impulsive and retarded, was playing on the roof with another boy who fell off and died.

At this point we can summarize this younger group of 14 children who neither intended nor expected the death that was the consequence of their activities. Except for the low grade defectives they reacted with shock which was not closely related to their basic psychiatric disorder. None however, was free, even before the incident, from very disturbing family, social and personal disorders. A few involved in fires were able to mature satisfactorily.

4. Death by stabbing with sharp instruments. This was caused by 7 boys ages 6, 9, 11 (two boys), 13 (two boys), and 14 years. The necessarily close physical relationship usually left little doubt as to the person involved. In 5 cases it represented an impulsive act of uncontrollable rage, with the weapon happening to be available or offered by another boy. The psychopathology will be discussed briefly with the next two groups.

5. Death by repeated blows with a heavy object. There were 6 boys in this group ages 8, 9, 13 (two boys), 14 and 15 years. It was usual that the first blow was impulsive like the above stabbing group, and then the blows were continued blindly or to quiet the victim. In one case a sex act had preceded the blows, in another a robbery.

6. Shooting caused death by 6 adolescent boys, 11-14 years. This act implied some planning and preparation or else defective judgment. In one case the death seemed entirely accidental, a friend being shot while the two boys examined a gun.

These last three categories, in which death was caused by striking with a sharp instrument, or repeated blows with a heavy

object, or shooting, included 19 of the 33 cases. Except in the case of the accidental shooting the victims were aimed at directly although often impulsively. This group showed the most pathology with schizophrenia, brain disease and/or epilepsy in all cases but three. These 3 were among the older cases in which such pathology had not been determined. Also in this group only 4 of the 18 boys were under 11. In this group consequently we get the reaction typical of puberty or of the young adolescent boy. This represents an attempt at denial, suppression of anxiety and guilt, amnesia and various repressive phenomena. Such pseudopsychopathic defenses (7, 8) may mask the basic schizophrenic picture or organic or epileptic disorganization for a while. However, several of these boys who showed "no psychosis" at the time of the examination or court hearing and were placed in correctional institutions, subsequently were found to become psychotic and transferred to mental hospitals or hospitals for the criminally insane and were diagnosed schizophrenic and/or epileptic.

Of equal interest is the evidence that 3 boys developed clinical epilepsy with convulsions some months after they committed the fatal act. Records of EEG's are available on 15 boys. Five were reported normal. Ten were pathological, indicative of epilepsy. In 3 boys the EEG disturbance reached its maximum in mid-adolescence and tended to become normal in the years the boys were under treatment in a controlled environment and received anticonvulsant drugs. But under emotional strain they were liable to explode and tended to seek isolation to control themselves.

Five adolescent boys had accomplices. In 2 cases, a weapon was furnished by one boy to another in a fight. In the other 3 cases it could never be determined which of two boys was responsible for the fatal blow or shot.

Six boys caused 2 deaths each and one boy, 3 deaths. With one exception, these were young boys and the multiple deaths resulted from a single fire. In only one case in this series was a boy associated with two deaths (by drowning) at some months' interval.

The final diagnostic classification in-

cludes 3 familial defectives (1 low grade, 2 borderline), 12 schizophrenics (9 in childhood and 3 recognized first in adulthood), 3 epileptics (and a fourth possibility), 7 chronic brain syndromes without epilepsy but impulse disorders, and 10 psychoneurotic depressions reactive to the situation.

Fifteen of these 33 boys and girls had psychiatric evaluation preceding the incident that led to the death of the other person or persons. In the majority of these cases there had been recommendations which had not been followed. In 5 cases there are on record official reports indicating that the boy was seriously dangerous. Of course, many other children have been described as dangerous who have not proven so, and in general we do have to remember that for a child to kill requires a certain combination of factors which include a disturbed, poorly controlled, impulsive child; the victim as an irritant, and an appropriate or handy weapon coinciding with lack of protective supervision.

However, there are certain dangerous symptoms of a psychiatric nature which should be considered as significant, especially when they occur in combinations, as follows:

1. Organic brain damage with an impulse disorder, and abnormal EEG and epilepsy (perhaps latent).

2. Childhood schizophrenia with pre-occupations with death and killing in the pseudoneurotic phase or with antisocial paranoid preoccupations in the pseudopsychopathic phase.

3. Compulsive fire-setting.

4. Defeating school retardation (reading disability).

5. Extremely unfavorable home conditions and life experiences.

6. A personal experience with violent death; thus having once been associated with a death, a child is always dangerous thereafter.

The psychodynamics of a child or adolescent held accountable for a death is a separate topic. Essentially the prepuberty child experiments with every method to prove to himself that death is not possible, while the adolescent tries to deny to others

both his guilt and feelings of guilt. Thus both are dangerous and misunderstood.

PROBLEMS FOR MEDICAL PRACTICE PRESENTED BY FAMILIES WITH A SCHIZOPHRENIC MEMBER¹

ROBERT H. DYSINGER, M.D., AND MURRAY BOWEN, M.D.²

The practice of general medicine on a special psychiatric ward encountered consistent difficulties which appeared to be manifestations of patterned emotional processes. The medical practice was one part of the clinical services offered a series of family groups with a schizophrenic son or daughter who participated in a project designed to study the emotional problems of the family unit from the vantage point of a long term psychotherapy. The consideration of the difficulties in the medical situation led to an effort to describe and conceptualize characteristic modes of relating of the family members in much the same way that difficulties in psychotherapy are studied as derivatives of emotional processes.

The project of which this work was one part has been described elsewhere (3, 4, 5). A series of 7 family groups consisting of both parents and a schizophrenic son or daughter participated for periods ranging from 4 to 33 months. The clinical work centered in a psychotherapy designed for the family unit. During the period of treatment the families lived on a special psychiatric ward operated by the project staff.

The medical work was carried out in a ward clinic operated by a psychiatrist on the project staff. This service was supplemented as indicated with consultation and other clinical services easily available in a large medical research center. The clinic was structured to operate as much as possible like an outpatient service. The responsibilities of the clinic were carefully defined to distinguish them from psychiatric functions. When an emotional problem was presented for medical attention, the responsibility of the clinic was con-

sidered discharged when the nature of the problem had been recognized. The treatment of emotional problems was a psychiatric responsibility, and many things commonly handled symptomatically in medical practice were, in this situation, matters for attention in psychotherapy. The doctor necessarily dealt with those emotional problems that operated to impair the medical functioning of the clinic. The experience over a 3-year period was that intense emotional forces were consistently present which could cause difficulties of this kind.

The total clinical situation afforded continuous direct observation of the functioning of each individual in relation to his family and others both in psychotherapy and on the ward; this provided a view of ongoing family functioning in which the relating in the medical situation could be seen in its current context. It appeared that the turning to and using of medical services was often to a striking extent an enacted emotional process which took the form of an interest in medical diagnosis and treatment.

The presence of such a problem was of practical relevance since significant, poorly defined medical problems were not uncommon especially in the parents, and effective medical service was often clearly indicated. The use of the medical setting by the family members for emotional purposes was often so intense as to make it difficult for the doctor to function responsibly as a physician. This was the case whether or not significant medical problems were present, but was minimal on the few occasions of actual medical emergency. The process of settling even trivial medical matters in a satisfactory sensible way was often laborious and difficult. These difficulties were characteristic in the medical work with the parents and the schizophrenic sons or daughters, but were rarely experienced with normal siblings. The histories indicated that the families' use of medical serv-

¹ Read at the 115th annual meeting of the American Psychiatric Association, Philadelphia, Pa., Apr. 27-May 1, 1959.

² Respectively, Psychiatrist, and Chief, Family Study Section, Clinical Investigations, National Institute of Mental Health, National Institutes of Health, U. S. Public Health Service, Department of Health, Education and Welfare.

ices in the past had been similarly involved in acted out emotional issues.

An example of the problem :

A mother had avoided serious medical consideration of a lower abdominal pain associated with the menses, of gradually increasing intensity over several years' time. She was anxious and tentative in approaching the clinic about it. A consultant in gynecology was asked to examine her. He found a pelvic mass and recommended examination under anesthesia, D&C, and laparotomy if indicated. With no mention of it on the ward, the mother consulted practicing gynecologists during visits to the city. One doctor called to describe his experience. He said that the mother had been unwilling to provide a history and asked for his professional opinion on the basis of examination only. He said he had done the best he could for her under difficult circumstances and asked to be informed of the findings if surgery was done in order to check his clinical impression. Later a laparotomy was performed and a rather large fibroid uterus successfully removed.

The numerous difficulties in the medical situation take on some order when seen as manifestations of specific emotional processes. Many observations indicated that the parents and the schizophrenic child discriminated poorly between intense feelings of helplessness and anxiety on the one hand and evidences of medical problems on the other. Much of their functioning appeared to follow from an assumption that feeling helpless was equivalent to being ill, and not feeling helpless was equivalent to being healthy. For example, a person could notice something physical and estimate it to be of no consequence. The estimate might be accurate or not and yet be largely in the service of a denial of feelings of helplessness.

By defining the characteristic ways the family members were dealing with intense feelings of helplessness in the medical situation two general modes of functioning are identified. The first and more common is described as an acting out of feelings of helplessness, the second as an acting out of a denial of such feelings.

The first mode of functioning, was characteristic of the mothers and the schizophrenic sons or daughters and was also

common for the fathers. It could be gross or so subtle as to masquerade for sensible action. The person related himself at each step of his dealings with the doctor in a way that accented helplessness. The decision to arrange an appointment could be avoided and the doctor's attention sought outside the clinic. This took the form of vague allusions to health matters in the context of a social greeting, acting sick or speaking of symptoms to others in the doctor's presence, and messages about vague ailing that the doctor heard as a rumor from others. The doctor could later discover that his response or lack of it had been given the weight of a professional opinion. Under such circumstances, there was ambiguity about whether or not the person was dealing with the doctor in his professional capacity. This ambiguity was frequently present in clinic appointments also when the person related himself as though he were in a social situation.

In speaking of his problem the person emphasized illness. Physical experiences and incapacity were elaborated beyond the actual difficulty. Medical terms were used authoritatively as though they adequately defined the situation. Past histories were distorted and past medical opinions and diagnoses introduced to document a picture of major illness. The emotional tone was commonly grim, urgent, and serious and could be imperiously demanding, plaintive, or simply insistent. This feeling was infectious and could tend to hurry the doctor into a view that the problem was actually an emergency. Medical inquiry about specific points and attempts to confirm impressions often met with obtuseness, vagueness, irrelevant elaboration, helpless unresponsiveness, or pressure for treatment.

When the doctor stated an initial clinical impression, the patient often became more thoughtful and at times decided to postpone medical work. A statement that diagnostic study revealed no evidence of a medical problem was often followed by a critical point in the clinical relationship. When a definite diagnosis was made it tended to be seen as the source of all problems. Medical treatment was often complicated by vagueness about symptoms

and pressures to prolong the use of medications. With the completion of treatment, a similar critical point in the clinical relationship was often reached.

At such critical points the person could create an unmistakable impression that he found the doctor unsatisfactory. This operated as an intense pressure to alter medical opinion to accommodate to emotional goals. The doctor seemed to be faced with the choice of losing working contact or compromising his best judgment. When such a point was reached the extent of the emotional use of the medical situation was unequivocally apparent. This anxious encounter between the emotional process and medical judgment could then resolve toward a more adequate recognition of the actual problems.

Throughout the medical relationship, the acted out helplessness appeared to maintain an emotional pressure to induce the doctor to assume a very great responsibility for the intense feelings by virtue of a diagnosis of illness. The person functions as though the action message is—"I feel intensely helpless, therefore I am ill. The doctor must recognize this, and when he has agreed, I then have an answer to my problem." The finding of any physical condition is one of the things that the doctor can do which appears to be taken as at least a token concurrence.

A characteristic example:

A mother in her 50's arranged an appointment several weeks after the family arrived. In the early weeks on the ward she had often commented about a variety of ailments. In the initial appointment she spoke with an urgent plaintiveness of pains in the neck. Persistence by the doctor developed a reasonably trustworthy history out of much diffuse talk. After a local examination a preliminary clinical impression was conveyed. The mother responded by repeating her own diagnosis as though to ask the doctor's assent. When he replied that his impression was somewhat different, the mother introduced another problem. Further diagnostic study over a number of weeks revealed a minor chronic medical problem which was not responsible for the long standing distresses of which she complained, and supported the view that these were on an emotional basis. The mother's acted out presentation of herself as a chronically ill helpless

woman made for difficulty in evaluating her actual medical condition.

A second mode of functioning is described as an acting out of a denial of feelings of helplessness. It was characteristic of the fathers, occurred also in mothers, but was not seen in the son or daughter. Problems were presented in a manner that emphasized the health of the person. Symptoms and incapacity were minimized out of proportion to actual difficulty. Past histories were distorted, the negative findings from previous medical check-ups emphasized, and the value of previous medical efforts minimized to support a picture of physical health. The possibility that a problem was psychological could be given prominence. The emotional tone was commonly casual, friendly, jocular, and appealing, and tended to lull the doctor into a premature view that no problem existed. Medical inquiry encountered vagueness about simple facts, plausible explanations, reassurances that the doctor need not worry, and when anxiety mounted, actual retreating. An opinion that a medical problem existed was the occasion for an anxious point in the clinical relationship. The acted out denial could continue into the treatment situation in the form of a casualness about treatment measures and unreliable reports of progress.

The emotional pressures appear to operate to induce the doctor to assume a responsibility for problems with feelings of helplessness by virtue of a diagnosis of health. The person acts as though he were conveying the message, "I am almost certain that I am not helpless, therefore I am in good health; a doctor must recognize this and when he has agreed I will then be certain of my answer to the problem."

A striking example from the medical history of a father:

After a period of some weeks during which he had noticed difficulties in an important sense organ, he casually mentioned them to a physician friend. His friend apparently sensing that the matter might be of some moment examined him and quickly recognized a serious problem. Appropriate attention from an outstanding specialist was promptly arranged. The indications were that the serious loss of

function that resulted was largely a consequence of delay in arranging appropriate medical attention.

On many occasions two or more family members were active about a medical matter. A variation of the acting out of feelings of helplessness could be identified in these situations which differed in that the problem was seen to exist in another rather than in the self. The most common form was a parent's action from concern for the schizophrenic son or daughter, the mother more commonly than the father. The mother's acted out concerns about the father were also significant.

In some situations the concern for the other brought about the medical consultation. In other situations, medical work already initiated by one member could become the focus of the acting out process of a second. The second member might even move to displace the other from his position of dealing with the doctor about his own problem. In a milder form he could simply invite himself to be also present at the other's appointment. The member whose health was being considered might accept the concern of the second member as his own; might go along with it without acceptance; defensively oppose it, or on occasion maintain his own view. The doctor was often looked to for a resolution of the intense differences.

The emotional pressure in this other appeared to operate to induce the doctor to assume a great responsibility for feelings of helplessness by virtue of a diagnosis of illness in the other. The person functions as though he were saying, "I feel helpless, it is because he is ill; a doctor must agree with me, and when he does, I then have an answer to my problem." The most prominent and intense of all the situations involving more than one member were those in which one or both parents acted out intense feelings of helplessness externalized as a medical problem seen in the son or daughter.

SUMMARY AND CONCLUSIONS

Medical practice with 7 families with a schizophrenic son or daughter regularly

encountered difficulties in accomplishing medical evaluations and treatment. The use of medical services by the parents and the son or daughter was extensively involved in intense emotional processes. Two modes of relating are described as an acting out of feelings of helplessness and an acting out of a denial of these feelings. A variation is described in which the acting out of feelings of helplessness took the form of a concern about another.

The emotional pressures tended to lead to inaccurate medical overdiagnosis and overtreatment in response to the acted out feelings of helplessness and to inaccurate medical estimates of good health in response to the acted out denial pattern. When medical findings differed from the emotional view, the clinical relationship could reach a difficult point. The problems in the medical experiences appeared to be one clear evidence of general processes pervading the family emotional life.

THE GENERAL PRACTITIONER AND THE PSYCHIATRIST¹

FREDERICK LEMERE, M.D.² AND AUSTIN B. KRAABEL, M.D.³

We psychiatrists sometimes overlook the fact that the major portion of psychiatric care is being handled by the general practitioner. It therefore behooves the psychiatrist to try to understand and help the generalist with the problems he encounters in this field of medicine. With this in mind, we have made a survey of the attitudes of some general practitioners toward psychiatry and psychiatrists.

A questionnaire was sent to 600 members of the Washington State Academy of General Practice. The comments contained in the 416 questionnaires that were completed and returned form the subject of this report.

RESULTS

PSYCHIATRIC EDUCATION

Sixty percent of the respondents felt that their psychiatric training in medical school was reasonably adequate for their general practice needs. This was enhanced by subsequent postgraduate courses and reading but their own clinical experience formed the main basis for their psychotherapeutic endeavors.

Some typical criticisms of their psychiatric education were as follows:

Too many cases were shown of psychoses, which we refer anyway, and not enough attention was given to the usual run of office cases such as anxiety tension states.

Our course was impractical with too much theory and almost no demonstration of ordinary counseling techniques such as I have to use every day in my practice.

Psychiatrists should keep on teaching us at our county medical society or hospital staff meetings, but mostly with our own patients that we refer to them.

I would like to have more round table dis-

³ Past President of the Washington State Academy of General Practice.

cussions of actual problem cases instead of formal postgraduate lectures.

PSYCHIATRIC PATIENTS IN GENERAL PRACTICE

The respondents generally seemed to be well aware of the emotional component of illness.

Anyone who is sick is bound to be more or less upset and vice versa. I try to give all of my patients what moral and emotional support they need.

The percent of general practice that was predominantly psychiatric averaged 24%. The respondents estimated that on the average they could take care of 78% of their psychiatric patients themselves. Fifty-one percent enjoyed taking care of their psychiatric patients as much as caring for their other patients.

The main complaint about psychiatric patients in general practice was that they take too much time, and that they are difficult patients to help.

These patients take a lot more time and are less remunerative than other patients.

My results with these patients are hampered by the fact that often there is not much to work with or the environmental pressures are so overwhelming, and there is not much I can do to correct these.

PSYCHIATRIC REFERRALS

Sixty-nine percent of those who replied would like to refer more of their patients to psychiatrists. They hesitate to do so, however, because of the expense to the patient (72%), patients often resent it (43%), the lack of available psychiatrists (32%) and the failure of psychiatrists to have been of much help in the past (25%). Some typical comments regarding referrals were:

The patients who need psychiatric care the most, often resist such a suggestion. It is often hard to get a patient to accept an emotional cause for his illness and I have to approach the problem obliquely or lose the patient.

I would like to refer more patients but only the well-to-do can afford psychiatric care and

few of my patients fall in this class, especially when the results are often uncertain.

Seventy-two percent of our respondents spontaneously complained of the lack, or the inadequate nature, of psychiatric reports.

Psychiatrists should keep the family doctor informed of the patient's progress. Too often we never hear from the psychiatrist at all.

Few of the psychiatrists ever tell me what is really wrong with the patient or how I should proceed with treatment.

OPINION OF PSYCHIATRISTS

Twenty percent of the respondents were more critical of psychiatrists than other specialists. Of those who were critical, 41% felt that psychiatrists are unrealistic, 33% that they are too unstable themselves and 27% that they seldom helped their patients. Some typical comments were as follows :

Only too often my patients tell me that the first interview with the psychiatrist has been a discussion of fees to be paid. I do not practice this way nor do any of the other doctors I know.

Psychiatrists should be doctors first and psychiatrists second. We never see them at staff or medical meetings.

I get up at 3:00 A.M. to see patients yet when I have an emergency psychiatric case, the psychiatrist's secretary won't let me talk to him and when he eventually does call back he can't see my emergency patient for two weeks.

Surprisingly, 36 of the respondents spontaneously criticized psychiatrists for giving too much electroshock and drug treatment and not enough psychotherapy.

It is hard to find a good psychiatrist. Some of them want to give most of the patients I refer a Freudian psychoanalysis. Others rush them into shock treatment and tranquilizers when what I had in mind was some experienced counseling for the patient.

While most of this paper has dealt with adverse criticism of psychiatrists, the general tone of the respondents was sympathetic and understanding of the psychiatrist's special problems.

Most of the respondents felt that the general practitioner should be better informed of the psychiatric field. This is a long way to go.

It is encouraging to note that the younger respondents were better satisfied with their psychiatric training, received a greater proportion of their practice as psychiatrists in nature, and felt they could, and would, take care of a greater percent of their psychiatric patients as compared to the older practitioners. It is evident that progress is being made in this field but much remains to be done to bring psychiatry up to the level of other specialties in the eyes of the generalist.

SUGGESTIONS

1. Undergraduate as well as postgraduate education should emphasize the clinical demonstration of borderline office-type psychiatric cases as well as classical textbook cases.

2. More consideration should be given to teaching counseling techniques. Most of our respondents felt that the maximum time they could spend with each of their psychiatric patients was one half hour a week. Intensive psychoanalytically oriented procedures are obviously out of the question for the general practitioner.

3. Psychiatrists must be more conscientious, realistic and helpful in sending their reports to the referring generalist.

4. Psychiatrists should explain the reason for such unusual medical practices as charging other doctors and their families collecting fees before prolonged psychotherapy is undertaken, not answering other doctors' calls while in a therapeutic session or refusing to take patients who have a poor prognosis such as alcoholics or psychopaths. Better yet, we might consider changing some of our procedures to bring them more in line with the accepted standards of our medical colleagues.

5. The most obvious need is for more psychiatrists and better therapeutic techniques so that more patients can be helped at less cost to the patient.

COMMENTS

The increasing acceptance of psychiatry by the public has been due to orientation

regarding the facts of mental illness. With current efforts under way to achieve this at the lay level, it seems worthwhile to review some of the obstacles and misunderstandings that persist within the "family" of our own profession. The rapport used by psychiatrists with their patients might well be employed "at home" to strengthen intra-professional ties. One example of such an effort is the American Psychiatric Association-American Academy of General Practice Joint Liaison Committee.

That obstacles exist to mutual understanding has been demonstrated by the difficulty of these two groups in laying the groundwork for a free avenue of communication. One of the problems in which a common denominator has been elusive is the tempo of general practice as compared to that of the practice of psychiatry. The suggestion has been made that the general practitioner set aside one afternoon or evening a week for his psychiatric patients. When one considers that most generalists see from 40 to 60 patients a day, it should be obvious that this would impose an impossible strain on the practitioner whose much needed time for family and recreation is already in jeopardy.

Our common ancestral prototype, the old-fashioned country doctor, also saw 40 to 60 patients a day and yet he demonstrated an instinctive understanding of human frailties that gained for him the enduring respect of the American public. Since his pharmacological specifics were limited, it is apparent that psychotherapy, crude or otherwise, was his most effective tool. Psychiatry in its embryonic struggles has lost touch with this homespun beginning and has left the generalist the difficult task of trying to adapt the psychiatrist's hour-long techniques to a practice that cannot allot such time to a given patient. Improvement in psychotherapeutic techniques that would give better results in shorter time is necessary if psychiatry is going to keep up with the advances that have been made in other fields of medicine. It has been suggested that a solution of this problem would benefit the overworked psychiatrist as much as the overworked generalist.

The spectre of psychiatric fees received

its full measure of criticism by our respondents. Many of those, however, who felt that psychiatric fees were out of line, paradoxically, declined to care for these same patients on economic grounds. Somewhat like the pot calling the kettle black?

The often heard complaint against psychiatric jargon was also raised. The generalist feels that he has important functions that take precedence over learning unneeded phraseology, and that communication between psychiatrists and other doctors could be greatly improved by a more medically oriented terminology with gain rather than loss of professional stature.

In the matter of referrals, there sometimes arises a situation in which the psychiatrist refuses to accept a patient because of finances or a poor prognosis. The generalist compares this unfavorably to his own sense of professional responsibility to hopeless cardiac patients or terminal cancer victims.

We could go on indefinitely, but we will conclude with some quotes from the questionnaires that will leave some food for thought.

No person is all mind or all body. I cannot separate the two. I'm afraid many psychiatrists forget the physical.

I cannot charge these patients commensurate with the time they take. Unlike the psychiatrist, I have a tremendous overhead to pay before I can even break even.

Do not underestimate the general practitioner's ability along these lines.

Psychiatrists should be more human and a friend to their patients. They are afraid their patients will seduce them.

I am less critical of psychiatrists than other specialists because they have more difficult patients to treat.

Many times one of the family comes in to discuss the case. I should be able to help but the psychiatrist has been incommunicado! Ours is a difficult position as the uninformed middle man.

The psychiatrist often fails to check with me regarding the environment and goes on just what the patient tells him. I am familiar with the whole picture and background of the case.

Stop acting aloof, allow yourselves to be seen and let's get acquainted.

SUMMARY

1. Sixty percent of 416 general prac-

tioner respondents felt that their psychiatric training was reasonably adequate. A desire for more presentations and informal discussions of office-type cases was expressed.

2. Generalists are in need of more instruction in counseling techniques.

3. Twenty-four percent of general practice was considered to be primarily psychiatric in nature. The respondents estimated that they could take care of 78% of their psychiatric patients themselves. The main complaint about psychiatric patients was that they take too much time and are often difficult to help.

4. The main difficulties with referring patients to a psychiatrist were the expense

to the patient (72%), resistance on the part of the patient (43%) and lack of available psychiatrists (32%).

5. The main complaints of these generalists about psychiatrists were their lack of availability and the inadequate nature of psychiatric reports to the referring doctor.

6. That progress is being made was indicated by the fact that the younger general practitioners were better satisfied with their psychiatric training, and felt that they could and wished to take care of more of their psychiatric patients as compared to the older practitioners. Some suggestions are made for improving the help that the psychiatrist can give to the generalist in this important area of medical practice.

RESEARCH IN HUMAN SUBJECTS AND THE ARTIFICIAL TRAUMATIC NEUROSIS : WHERE DOES OUR RESPONSIBILITY LIE ?¹

BERNARD BRESSLER, M.D., ALBERT J. SILVERMAN, M.D.,
SANFORD I. COHEN, M.D., AND BARRY SHMAVONIAN, Ph.D.²

The authors are engaged in a research project at Duke University³ dealing with isolation and sensory deprivation which uses human subjects selected at random. These subjects evidenced no gross psychopathology. The experiment is, on the surface, a comparatively simple one. Without previous instruction the subject is placed in a small, soundproof, completely darkened chamber for a period of two hours, at the end of which he is interviewed in the chamber to obtain his immediate impressions and reactions. Following this, he is seen outside the chamber by another interviewer, who questions him further on the cues picked up in the initial interview (which is taped). Then the subject fills out a comparatively simple written questionnaire regarding his impression of the experiment. On the day following the experiment he meets with a third interviewer for evaluation of his memory of his reaction to the experiment and also, generally, to determine how he has handled the total experience.

Reviewing our experience with one subject, a seemingly well adjusted, bright young woman obtaining her Ph.D. in psychology, we were confronted with an important problem which deserves considerable discussion and sober thought. A brief description of her progress during and following the experiment will indicate the exact nature of our concern.

It was quite apparent from the initial interview inside the chamber that the subject was experiencing a great deal of anxiety, and as she described it,

"My heart is beating quite fast." She described the feeling of "trying to get some kind of anchor; some kind of bearing," since all of her visual cues were gone. She reported periods of uneasiness, reassuring herself that she didn't have claustrophobia, and a headache which lasted for a short time. It was readily apparent (as is typical for almost all subjects) that she had no idea of the time elapsed despite her intellectual realization that she hadn't been in the chamber very long. When asked for a specific time estimate of her isolation she replied "Oh, hours." Her initial appearance was that of a perplexed, frightened, uncomfortable and anxious person. Her thinking process was quite slowed, and there was a great change in her verbalization and general speech patterns. As the interviewer entered the chamber her first impression was that he looked much larger than his actual size, and it was at this moment that she began to feel anxiety. Also she produced several bizarre fantasies: one about a submarine and another, derived from a science fiction story, about people locked in a room where they were slowly frozen to death. She required roughly an hour and a half to recover her normal intellectual functioning since, as she stated, "I was bewildered."

Following the isolation experience the subject described her feelings as "being shaken up inside." She said that she had a tremendous impulse to find someone she could trust and tell him "all about it." On her arrival home she was very hungry, something quite unusual for her, since she rarely eats at night. She played a few records and fixed something to eat although "it wasn't real hunger, just something to do." Finally, after great difficulty she went to sleep, awaking in the morning to find that the sheets had all been kicked away from the bed.

In the interview the next day she further elaborated some of her isolation fantasies. For example, she had the thought that "Maybe there was only two or three hours' worth of oxygen in the room." She identified herself with sailors in a submarine, a submarine which was obviously in danger. She recalled skipping from one dangerous situation to another and stated that she had concentrated on such situations. One of the dangers was "that the experimenter

³ Support from Contract #AF 49(638)-354 and NIMH Grant M 2061 for the work on which this paper is based is gratefully acknowledged.

walked into the room, and an enemy closed the door behind him. Of course, there were no locks. He couldn't get out, and the fellow froze to death." At times she had some near paranoid ideas, i.e., thinking that the room was deliberately overheated, that her headache was due to deliberate oxygen deprivation, etc. At one point she became very threatened and thought "Well, I'll play a trick on you. If I go to sleep, you'll get me out." She said she had tried sleeping, and actually it was at this moment that the experiment was interrupted, and an interviewer entered.

At first, "You know I couldn't answer properly. I had a feeling I had nothing to say. I felt slowed down. Then there was that tremendous thumping of my heart." She said that at one point she reviewed her past and present life but had no thoughts about the future. Although she had a lot of love fantasies, she was unable to describe them to the interviewer who had teased her in the past. She thought about the opera "Aida," in which Radames was put into a vault to die. Her reaction to the total isolation experiment was: "There was something fascinating about it. It's not entertaining like going to a movie, but it's something fascinating, it's like having gone through the war. I'll never regret having gone through the war and having had my experiences despite the fact that they were pretty uncomfortable. There is something about it that just fascinates me."

Some time elapsed during which we had no further contact with the subject. However, it was subsequently decided to retest this subject (and others) in order to further evaluate the material under different circumstances. The experiment was repeated exactly as before, except that this time she was told in detail exactly what would happen.

One of the most remarkable effects of this second isolation experience on the subject was:

"I said to myself now I can really get my fantasies going. In other words I didn't start thinking of the present as I did before; this time I tended to wander more towards the past and towards the future, towards trying to solve problems. You know it seemed a lot longer this time, it was much harder for me to stay awake, and I was much less alert."

Later she indicated that she was sure she fell asleep, despite her intention to stay awake and watch her fantasies, and although she had taken a nap earlier to avoid being sleepy dur-

ing the experiment. She also noticed a sort of focus in her thought processes. "Well, they were sort of level, then going up and down, up and down, like a slow wave. This is unlike before when there were lots of things which kept me alert." Further, she essentially described a tremendous amount of passivity and massive demand, which she grudgingly admitted were related to "having to avoid something." The subject indicated that she was quite surprised at her total reaction.

Her previous experiences in the chamber had been so vivid that she assumed that by "letting herself go" they would be even more vivid, yet actually they weren't. Another important factor of the isolation experience was that many of her thoughts were directly concerned with or immediately related to her childhood, particularly of a period of summer vacation. At one time she referred to the underwater submarine scene which she described earlier; note this was associated with a story she read at age 9 or 10 in which a heroic diver died after a very exciting episode.

Throughout the second experiment the subject experienced periods of boredom which puzzled her since they seemed to be completely out of control. Usually associated with the boredom were feelings of wanting to get out and a return to some of her projective thinking, for example, "I thought that the boys were holding me in here longer than they did before," (despite the fact that she had been carefully reassured that she would remain in the chamber only two hours).

She had many feelings of being in a dangerous situation, despite the reassurance that she had been through this before and that "nothing had happened." As this material was elaborated her ninth and tenth years of childhood became most important. During this time she had spent a vacation in the country, following which she had left her home in Europe to come to the United States. Associated with this move was much unhappiness since "I was perfectly happy. I mean I couldn't see why . . . the fact that . . . my friends were doing this. They said the United States was a place where we could live much freer than we were, yet I felt perfectly free."

It is to be noted that this woman was in a period of transition; she was leaving her present position, a very protective training program, to go on her own. This leaving was directly reminiscent by association of leaving her homeland in childhood.

One other interesting incident occurred during the second interview. At one time the subject suddenly felt as if the room were tilted and noticed that her head was tilted, too. Try as she might she could not right herself. Not until she forcefully "straightened" her head with her hands did the room resume its normal position.

In the interview on the day following the experiment the subject greatly elaborated the material reported in the previous interview. She described her experience as "a kind of numbness. In a sense all of my feelings were sort of on even keel." This is a secondary distortion. Despite her massive denial, she did experience moments of anxiety. She said in reply to a question that it was "as if I weren't responding to anything." This statement again exposes her attempted repression and—when this was unsuccessful—massive denial.

She reported an interesting dream in which "people were bunched together, people from my high school days and people that I knew (in her home country) as a little girl, and the people I knew here . . . I was sort of surprised. I thought to myself what on earth are all these people doing here, I haven't seen them for years."

The dream and her subsequent elaborations were associated to her memory of the vacation in the country before she came to the United States. Her feelings about the separation trauma were very much like her feelings about being separated from Duke. She said further about the experience in the chamber "I said I'd come back again. I didn't enjoy the experience but it was so weird; it was fascinating." (We never explained her excessive use of the word "fascination.")

Following this interview it was necessary to have another session because of a very peculiar symptom she developed.

She seemed to have lost sense of direction and was confused whether to take a left or right turn as she was leaving a room. This symptom was clearly related to her tremendous indecision over "where to go," i.e., the separation in the present was, in turn, related to the feelings of separation from her country as a child which had been stirred up by the isolation experiment.

Another subject reported immediately following the experiment that he had directed his thinking during the period of isolation. He said that thinking of specific events made him more comfortable and

that he found these thoughts reassuring since the darkness and silence were disquieting.

The subject, a medical student, mentioned that one of the things he had reviewed was an interview with a young patient the day before, and he implied that thinking of this kept his mind from other thoughts. The initial interviewer believed the subject to be more upset by the experience than he described, but there was no direct evidence thereof. Associations during the interview were only followed in terms of the immediate experimental situation for fear that allowing the subject to associate to past events might either (a) enhance any disorganization which the subject already felt or (b) allow the subject to escape into the past and "forget" the present provocative events. Furthermore it had been decided that extensive exploration should not be attempted during the first interview if the subject appeared to be confused, disoriented or extremely uncomfortable. When the subject was interviewed on the following day, he was considerably more comfortable although he still expressed much embarrassment and discomfort in regard to the previous day's experience. To reassure him the interviewer spoke of the many unusual thoughts subjects had during this experiment and pointed out that sometimes discussing these feelings and ideas allowed the subject to look at them realistically and feel more comfortable about them. At this point the subject remarked that not only had he been thinking about his young male patient, but that there were some sexual connotations. Furthermore, the previous interview conducted in the chamber just after the completion of the experiment was associated with sexual feelings he experienced in regard to the interviewer. He described feeling panic at this time and feeling panic at the previous thoughts about the patient but he had felt unable to report it. Certainly the experience acted as a traumatic event for this subject by bringing to the conscious level latent homosexual feelings and thoughts.

There is some evidence that these feelings have remained conscious. For several days thereafter and indeed, until the present time, this subject is unable to look directly at the interviewer and is apparently embarrassed when they chance to meet.

A female subject requested release from the chamber, and when this was not done rapidly enough, she located the emergency door and walked out of the chamber a

half hour before the official termination of the experiment.

In the interview which followed, the subject stated that she was beginning to feel restless and had had a certain amount of anxiety and fear although she did not consider the experience overwhelming. All of the interviewers noted that the subject's usual vivaciousness was replaced by an affective state which varied from flatness to irritability and petulance. She seemed extremely suspicious, exhibited poor judgment in the things she had expressed and the manner in which she expressed them. When she was first seen, she appeared quite confused and had the appearance of sleepwalking. This state lasted for several days, and a full month passed before she was her usual vivacious self.

During the interview on the following day the subject related that she had always been afraid of darkness and that this was particularly true for the past year since the death of her father; she insists that each night one or two lights be left on in the house, because she and her mother "are alone and some prowler might enter the house." She then described how she had attempted to resist this thought by thinking of pleasant things while she was in isolation. As the thought that someone might be "prowling on the outside" and that he might break into the chamber came closer to awareness, the subject's anxiety and restlessness increased until she had to leave the chamber despite strong inhibitions based on her desire to help and to please the experimenters.

DISCUSSION

It seems reasonably clear that the processing of these subjects in an experiment which was, on the surface, comparatively innocuous, acted as a traumatic event. This result is even more significant in view of the fact that the subjects were carefully chosen as individuals with "strong egos." Although intelligence and education are not necessarily the attributes of a strong ego, these factors plus our knowledge of the subjects had made us reasonably secure in our evaluations of them.

By definition the amount of psychic energy which one's ego is unable to master within a reasonable span of time is designated as a trauma; ordinarily there are protective barriers (i.e., the defenses) against the outcropping of such stimuli, i.e., id impulses. It is also known that there

are numerous instances in which the ability of the defenses erected by the ego to maintain usual or normal functioning is diminished. We believe this to be particularly true in the sensory deprivation experiment we have conducted in which we have introduced a temporary abrogation of usual ego functioning. In other words we deliberately (or artificially) deprive the ego of many of the usual activities and resources which help to keep its defenses intact. In our experiment the paralysis of voluntary motion and withdrawal of many of the usual sensory stimuli which guide the ego produce a strange, potentially dangerous situation for the ego. Under these circumstances, if the protective defense barriers break down, the ego loses its ability to react with purposeful reactions and anxiety, in one form or another will appear. Although the ego opposes the emergence of an id impulse that is equated with some dangerous situation by producing anxiety, it is equally possible, as indicated above, that the ego, unaware, is helpless or temporarily overwhelmed in the face of some conflict and this, in turn, produces anxiety. Thus we believe that the artificial abrogation of ego functioning markedly weakens the ability of the ego to utilize countereathesis so that repressed and conflictual material tend to emerge into consciousness. This is particularly true for those conflicts which might otherwise be handled slowly or more realistically but which can no longer be put off by a paralyzed and weakened ego.

Subsequently it is our feeling that the experiment produced a temporary artificial traumatic neurosis. Although the problems indicated were naturally latent, we believe they would not have emerged with the same intensity in ordinary circumstances.

In view of our experiences, and since it is clear that the trend in psychiatric research is toward the utilization of human beings as experimental subjects, we must ask: 1. What is our responsibility, irrespective of the terms—moral, legal, medical, etc.—used, towards the subjects? 2. How can we best protect subjects from traumatic reactions to an experiment? It is to be noted that our subjects underwent a relatively mild experience (or so it seemed) while

more "dangerous" situations can certainly be conceived. 3. What should be the criteria for the selection of subjects? Can we avoid those subjects who are "sick," or are they an integral part of our research?

It is our belief that, regardless of our research motivations, we have a responsibility to these persons as doctors, as therapists and as fellow human beings and must, in the future, make some provision for helping them with the inevitable traumatic reaction to experiments.

This attitude leads to the question of safeguards during research. Should research grants be extended to include the followup care of subjects in terms of time and money? Would followup care then be considered an essential part of research, or would it broaden the scope of research over and beyond its original purpose? The problem is immeasurably complicated when certain kinds of research (which conceivably could be traumatic) are undertaken by investigators who are not therapy oriented. Ideally, then, provisions must be made to include therapy-oriented person-

nel who may not be directly involved in the experiment in the research grant.

A further important complication occurs when research is done on a patient in therapy. It is extremely difficult to evaluate the effect of concomitant research on therapy; most dynamically-oriented psychotherapists, especially analysts, emphatically state that the introduction of a new artificial parameter not only adds to general resistances, on the part of the patient but can also serve as "a flight away from therapy." For this reason analysts were very reluctant for many years to allow psychophysiological studies to be made on patients in analysis.

CONCLUSION

In conclusion it seems that if we are to continue doing research in clinical psychiatry on human subjects, we *do* have a responsibility to the subjects, to somehow protect them against the possible traumatic effects of an experiment. How this might best be done should not long remain an unanswered question.

PSYCHOTHERAPY OF THE HOSPITALIZED ADOLESCENT¹

WILLARD J. HENDRICKSON, M.D., DONALD J. HOLMES, M.D., AND
RAYMOND W. WAGGONER, M.D., Sc.D.²

Undertaking the psychotherapy of adolescents always involves opportunities, hazards and challenges unique to this period of development. It requires methods which often differ materially from those used with adults or children, and which may stand in contrast to more usual concepts of treatment.

This paper and previous reports(4, 5, 6) represent some 10 years' experience with more than 300 patients between the ages of 13 and 18. During the past 2½ years, they have been treated on either the adult wards or on the 25-bed adolescent ward of the Neuropsychiatric Institute. Prior to this, all adolescent patients were treated on one of the adult units. The patients could be classified among all the major official diagnostic categories.

This report is concerned only with the inpatient psychotherapy of youngsters whose severe personal and family pathology required their separation from home for a period of hospitalization. As there are no very well-established treatment procedures in this field, the many dramatic adventures and mis-adventures provided by patients of this age have led us to the formulation of some tentative treatment principles.

INITIATION OF TREATMENT—ADMISSION PROBLEMS

Prior to the first outpatient contact, which marks the beginning of hospital treatment, these youngsters have usually found their entire world disrupted by the disintegrating influences of adolescence, by the inroads of illness on mental functioning, and by unsatisfactory family relationships.

Admission to a hospital poses further threats by removing the support gained from familiar, if manifestly intolerable home situations. For these and other rea-

sons, psychiatric hospitalization is associated with more exaggerated fears for adolescents than for any other group of patients. This fear and its concomitant resistance is, in fact, so usual that we have come to regard the presence of an accepting and cooperative attitude towards hospitalization as an ominous sign.

Parents are often even more frightened than their teen-age child by the prospect of his admission. Not only is adolescence a period of emotional upheaval for the youngster, but also a period in which any neurotic or psychotic potential in his parents is maximized as well.

All adults find it hard to react realistically with these attractive, threatening manipulative, anxiety-provoking youngsters. For the parents this may be quite impossible. At first parental anxiety over threatening symptomatology in the patient will often offset their anxiety over having the child hospitalized. At this time parents may be able to nominally "accept" (usually with private reservations, and often even with secret "deals" with the patient) the initial advice for admission. Maintaining the decision for the many months that hospitalization usually requires is quite another matter.

Time and again we have observed sharply rising parental anxiety as the patient improves and abandons the stereotyped modes of behavior for which the parents have a need. In many instances, treatment has been sabotaged after a promising beginning by parents removing the patient prematurely from the hospital.

As a result, we are more and more frequently requiring in selected cases that parents petition the juvenile court to assume temporary custody over the child as a condition of treatment. This supportive use of court authority to supplement intensive case-work treatment of parents may serve to deter, but does not necessarily prevent the parents from signing a child out against medical advice on a neurotically determined impulse. This procedure can

¹ Read at the 115th annual meeting of The American Psychiatric Association, Philadelphia, Pa., Apr. 27-May 1, 1959.

² Neuropsychiatric Institute, Ann Arbor, Mich.

actually reassure the parents, as well as the patient. The patient may feel more secure in his hospitalization, being relieved of the temptation to test his parents' reliability by pressuring them to remove him.

Although such active medical intervention obviously carries many risks and disadvantages, our own experience has led to the conclusion that any less vigorous approach may be utterly inadequate to the task at hand. From the very first the doctor must "take charge," demonstrating his willingness to invest unlimited time, energy, skill and medical authority to establish the necessary treatment program.

SETTING-METHODS OF THERAPY

The overall hospital environment, with its demanding school and activity programs, realistic social standards, and methods of dealing therapeutically with antisocial behavior, have been described in earlier papers (4, 5, 6).

In this setting, psychotherapy is conducted with infinite flexibility regarding frequency, duration, circumstances and methods of interviewing. A treatment plan is not based on formal diagnostic preconceptions, or the therapist's favorite theoretical orientation, but rather on the doctor's best estimate of the patient's ego resources and deficits at that time, and, of course, on reality circumstances.

The average adolescent is too busy "growing up" to waste energy on many of the therapeutic systems we find most interesting. He cannot afford any *elective* treatment of symptoms or conflicts. The principal subject matter of treatment is not so much psychopathology as "adolescence," with its need for therapeutic promotion of maturation in critical ego capacities.

Psychotherapy proceeds through resolution of emotional crises occurring principally between the patient and his doctor, and also between the patient, his family, other staff adults and fellow patients. Therapy concerns itself with "real things"—school, problems of the day, behavioral difficulties. All these are regularly discussed as the doctor regards every significant daily experience as a part of psychotherapy. Interpretive work with emotionally important experiences of the past is done only in

relation to these current, concrete essential activities.

THE RELATIONSHIP IN PSYCHOTHERAPY

The psychology of the adolescent and his treatment can best be understood in terms of the adolescent-adult relationship, the only framework in which we can study him directly. Although we may be aware of the adolescent's continuing hunger for infantile satisfactions, he cannot acknowledge it openly. This partially accounts for his need to be devious and manipulative in his relationships, particularly with adults. He must maneuver us into supplying his wants without making their exact nature public. The behavioral consequences of this are so very characteristic of the adolescent. They are reflected in his over-determined strivings for "emancipation," his ambivalently belligerent reaction to adults, his inordinate intolerance to any special concessions, or direct expressions of affection or proffered "help," and his highly strategic, disarming use of words and ideas in communicating with others.

In dealing with the necessarily strenuous treatment relationship, it is important to recognize that the doctor's most reliable ally is the patient himself. Beneath the smoke and noise lie the youngster's unconscious ego-ideals, his wish to like, respect and trust others and to receive the same from them, his adaptive ego mechanisms, and the vitally important promise of progressive biological maturation.

It appears that the best way to "build a relationship" with an adolescent is to avoid scrupulously any self-conscious effort to do so. That the therapist must frequently act as a frustrating, depriving disciplinarian always excites concern that such action will prevent the growth of a therapeutic relationship. It is often assumed that a patient's reactive anger to frustration is equivalent to hatred. Therefore, unpleasant but necessary intervention in the life of the patient is commonly undertaken by the therapist with considerable anxiety, and is often regarded as an unfortunate contaminant of the treatment relationship. Actually the disturbed adolescent can initially find great comfort in regarding his therapist as an unreasonable tyrant.

The doctor in neutralizing or remedying external problems which the patient has found too big to handle, and in acting without apology, threat or reluctance to assist his patient in any way necessary with the task of managing his own instincts, actually facilitates the kind of relationship which is prerequisite to any effective psychotherapy.

Insistence upon assuming any valid responsibilities in conducting a patient's treatment is one quality of the therapist's attitude which seems to be recognized regularly and deeply appreciated by the patient through the stormy vicissitudes of therapy. The patient who enjoys this kind of relationship with his therapist can usually successfully weather our inevitable errors of judgment, clumsy and inaccurate interpretations, and his own periods of symptomatic exacerbation.

PROBLEMS IN COMMUNICATION

The problem of communication may also best be approached through attempting an understanding of the inherently troubled relationship between the *adolescent* patient and the *adult* therapist.

We have recognized that the adolescent is in a terrible dilemma. He at times may feel a more intense need to depend upon adults than does a small child, but unlike the latter he cannot afford open acknowledgment of this need. He is compelled to garner surreptitiously cues which will indicate our attitudes toward him and our ability to perceive and supply what he needs.

So, although we meet with the patient for the nominal purpose of exchanging ideas through words, it is seldom that we hear a direct verbal expression from an adolescent in which the important feelings involved correspond to the literal content of his statement.

The importance of mannerisms, bodily attitudes, facial expressions, inflections, intonations, "acting-out" behavior, and other informative activity can hardly be overemphasized. That adolescents seemingly "talk" most directly via behavioral clues is well known. Learning to "read" behavior of the patient is a challenging task, but not nearly so difficult as developing appropriate

curiosity about meanings concealed behind fascinating verbal content which, in spite of ourselves we tend to take literally.

The adolescent's militant use of logical argumentation though partly an effort to assert himself as a power to be reckoned with, frequently seems to serve another purpose in his recurring struggle to come to terms with adults. When important personal issues are in the foreground he can plead his case with formidable logic which even an intelligent adult, who has his feet set off balance by the emotional intensity of the presentation, can find very difficult to assail. Even so, when the therapist is successful in sweeping aside all of the rhetoric with a simple, direct reference to the central issue, he may be amazed to find that his thundering antagonist is obliquely reassured, agreeable, and comfortably compliant.

In such instances it very often seems that he is far more interested in ascertaining his therapist's perceptiveness and capacity for honest expression than he is in winning a battle. An adult can be misled with astonishing ease by such verbal sleight of hand. When this occurs he is reduced to defending his own position with the same arbitrary, oblique sophistries which the adolescent wields with consummate skill. In doing this the adult loses a measure of self-esteem, will be inclined to react with defensive anger or avoidance, and has lost control of the treatment. In the light of such considerations, we find ourselves constantly pre-occupied with the "hidden agenda" seeking to penetrate the camouflage of our patient's logic, his emotional smoke screen, in an effort to (a) understand the essential communication and (b) matter of factly translate this into an idea he can understand without his feeling condemned or belittled.

The disturbed adolescent not only expects this degree of perceptiveness and directness in our approach to him, but he demands it. His uncanny sensitivity to our over-investment in words and ideas provides him with a potent defensive weapon. In his own exaggerated anxiety about treatment, he is ready to capitalize, for a time, on the therapist's often comparable anxiety level to seek a comfortable sanctuary in

intellectual discussion of his inner conflicts. This may lead to a kind of ritual treatment with its apparently rich psychological content and logical interpretations leading to new "insights." Unlike many adult patients, the adolescent usually will not permit us to go on interminably with such intellectually interesting but emotionally irrelevant verbal exchanges. Eventually his frustration and disappointment will become manifest in one way or another. His reactions usually either disrupt treatment or compel a more effective approach to it.

PROBLEMS OF INTERPRETATION

Concerning intensive, individual psychotherapy with adolescents, a few generalizations may be made.

Self-consciously analytical verbal interpretations, even though quite accurate and within the patient's conceptual reach, are subject to a variety of misapplications by him. He may correctly diagnose this approach as a reflection of our exaggerated interest in the treatment process itself, and capitalize upon this in the interest of resistance or secondary gains. Interpretations of defense mechanisms are ordinarily best directed at demonstrating that maladaptive symptoms, or behavior, exist. They do not aim at encouraging the patient to a full revelation of the unconscious conflict against which the defenses have been raised, but at encouraging more effective modes of handling the anxiety resulting from abandonment of old defenses. The adolescent probably has something close to a child's potential for invoking new ways of handling old problems. Great ingenuity is required of the therapist in helping the patient to realize this potential.

Even when the content of an interpretation is truly understood by the patient, it is still usually ineffective in modifying his adjustment. The rebellious, acting-out adolescent may fully agree with our interpretation of his behavior, but it is only when we are successful in reinforcing the words by curbing the behavioral expression itself that he is able to appreciate these words as referring to immediate, proven reality. Eissler has observed⁽²⁾ that while the delinquent is capable of abstraction, only the concrete has emotional meaning

for him. Our experience has shown this to be equally true of all disturbed adolescents and that furthermore it points up an essential principle in their treatment.

A source of effective non-verbal interpretation is in the central attitudes of all staff members toward the patient. He enters treatment with a powerful compulsion to maintain his neurotic equilibrium through established patterned responses, and without adequate regard for altered external conditions. In this socially organized setting (as opposed to an artificially permissive, self-consciously therapeutic atmosphere) he encounters a substantial resistance to his acting-out in accordance with his existing, neurotic conception of reality.

Here, the delinquent boy with swagger, D.A. haircut and long side-burns gets an entirely different reaction than he has been accustomed to having. As the defensive worth of his actions is undermined, he experiences disappointment and anxiety, and is forced to recognize a disparity between his own fantasies about the meaning of his behavior and the emphatically expressed attitude of a new group of adults. In this sense, the milieu is interpretive. Its specific functions in this regard must be actively maintained by the psychotherapist's constant work with the staff.

It should be emphasized that the success of this kind of interpretation is critically dependent upon the patient's ability to regard the staff, and particularly his own doctor, as extremely reliable, consistent and straightforward. We have come to feel that in this work, we must try to approach the patient with a degree of honesty which ideally excludes even the conventional deceptions and duplicities of ordinary adult society.

Very frequently some elliptical, essentially non-verbal communication will be more effective in bringing the patient to one of those painfully real understandings of himself than will careful intellectual dissection. Some things are best left implicit, mutually understood by therapist and patient.

It often becomes quite important to get at the roots of some extremely disturbing problem at a time when the patient is unable to participate in a reasonable discussion, and circumstances—as for example,

bouts of uncontrolled behavior—will not permit temporizing. At such times, the therapist may make a number of intelligent “guesses” about the origins of the acute problem, and present these to the patient *as such*. He offers tentative interpretations about possible meanings and awaits responses which will point the way to further and increasingly fruitful “speculations.”

We frequently talk with the patient about some of the ideas or strivings which are ordinarily unconscious with most adults, but not with the intention of helping him to recover and resolve infantile conflict. Rather, after recognizing that his guardedness results from feelings of guilt and shame over a conscious preoccupation, we refer to it openly only for the purpose of demonstrating to the patient that we are not frightened, horrified or accusatory, as he had anticipated.

The adolescent will obviously experience important transference distortions in the therapeutic relationship. At the same time he is necessarily entertaining a number of very realistic expectations from the *therapist-as-an-adult*, who is furthermore a most important parent-like figure in the patient's current life.

It therefore becomes imperative that when the patient is expressing a particular need in relationship to his doctor, such as a feeling of helplessness, or the inability to make a particular decision, that the doctor judge correctly the degree to which this represents a transference distortion persisting from early childhood situations, and the degree to which it may reflect the patient's realistic appraisal of his own current incapacity.

Generally, that which is transference is dealt with appropriately as such, often with limited interpretations designed to point up anachronistic distortions of reality. On the other hand, those needs of the patient which belong naturally to this age and situation and state of ego functioning must be fulfilled by the therapist, either directly or indirectly.

SUMMARY AND CONCLUSION

Experience in psychotherapy with over 300 hospitalized adolescents is described by brief reference to several important aspects of treatment.

The patient's admission to the hospital is regarded as a critical phase in treatment. Here the doctor first accepts that high level of responsibility for the patient's welfare which must be maintained around-the-clock during hospitalization, and generally continued long after discharge. This is usually required to assure the patient of continued treatment despite powerful opposing forces from within himself, his family and sometimes others. By taking care of his patient's realistic needs, without expectation of immediate personal reward, the therapist incidentally lays the groundwork for the gradual development of a relationship which is in itself therapeutic and which later actually supports verbal psychotherapy in the more conventional sense of the word. The therapist not only may, but must personally exercise needed authority over the patient. He is constantly supported in this by the supervisor of psychotherapy, who is necessarily also the ward administrator.

The therapeutic hospital milieu was carefully developed with the understanding that the ego continues to shape itself against the demands of reality, and that the creation of an artificial freedom from reality is justified only in so far as the patient is genuinely unable to respond to realistic demands with personal benefit. It is recognized that there are levels and kinds of responsibility. Whatever a therapist expects his patient to contribute to his own treatment, by coping with unmodified realities, must be determined by the doctor's own best estimate of his patient's abilities.

Treatment of the adolescent is a highly interpersonal process. Attention to the qualities and vicissitudes of *adolescent-adult relationships* is seen as the best means of understanding the processes of psychotherapy with patients in this age range. This is probably also the most useful framework in which to study the psychology of adolescence generally, as we rarely have an opportunity to observe them directly except in relationship to ourselves. We never see them in the kind of theoretical vacuum which is so often assumed in textbook discussions of them.

In treatment, primary importance is attached to any efforts which foster the

normal maturational processes of adolescence. Psychotherapy, though derived from psychoanalytic psychology, emphasizes measures which favor ego-synthesis without extensive analysis of infantile conflicts.

Some of the universal sources of tension between the adolescent and the adult are mentioned with particular regard to resultant distortions in communication. The recognition of essential verbal and non-verbal communications is discussed as a prerequisite to successful treatment. There are many complex countertransference problems which are characteristic of therapy of adolescents, and which ultimately will require detailed study.

Finally, it is proposed that adolescents, for a variety of reasons peculiar to their age, tend to compel effective treatment. They appear to be much less tolerant of ritualized treatment than adults, and because of their physical size and the strength of their drives, they can convey the magnitude and urgency of their intolerance much more impressively than the child.

THE RELATIONSHIP OF SCHOOL PHOBIA TO CHILDHOOD DEPRESSION

STEWART AGRAS, M.B., B.S.¹

During the last few years a fairly consistent psychodynamic pattern accounting for the genesis and development of school phobia and more or less applicable to the individual case has been outlined and detailed by various workers on the North American continent. This paper is concerned with a neglected aspect, namely the importance and frequent occurrence of depressive anxieties in both the affected child and one or both of the parents, an affective disorder which appears to lie behind the presenting symptoms. In reviewing the literature on school phobia only one reference to the frequent occurrence of depression in these cases was found, in a paper on manic-depressive disorders in childhood by J. D. Campbell (1) who points out that a great many children who develop school phobia are really suffering from what he terms an endogenous depression.

REVIEW OF THE LITERATURE

Johnson and her co-workers (5, 6), the first to describe the psychodynamic development of school phobia, pointed out that the basic problem in the child is separation anxiety which may be manifested as an inability to go to school, or as homesickness, or refusal to visit relatives. The relationship between mother and child is described as one of unresolved dependency, characterized by mutual hostility and dating back to the earliest years of childhood. The outbreak of school phobia depends upon some type of marital stress such as infidelity on the part of the husband, financial threat, or severe sickness together with a simultaneous threat to the child's security such as an illness, accident, or a disturbing change at school. It is postulated that these happenings cause an increase in the child's dependency needs which are exploited by the mother in a

vicarious way. In this regressive type of relationship the child's hostility towards the mother is aroused and becomes displaced onto the teacher or some other part of the school situation, leading to phobic avoidance of school, and refusal to separate from mother lest any harm befall her.

A group of 53 cases seen at the Judge Baker Guidance Centre largely confirms this psychodynamic outline (2, 12). The workers there divide the syndrome into two sub-types, those presenting before adolescence who tend to conform to the dynamic pattern described above, and termed neurotic type, and those who present at an older age whose symptom it is felt is but an aspect of a more widespread and insidious disturbance, termed the characterological type. The families are described as being "caught in an oppressive vortex of illness, death and disaster dominated by powerful grandparents and aunts." They feel that the mothers manifest a strong primary affection for the child but have deep fears about their competence as mothers, as a result of which they develop an over-protective attitude towards the child thus promoting a dependent clinging attitude from the child who also makes excessive demands on her. This leads to a vicious circle of repressed hostility, and is the basic relationship leading to separation anxiety. This type of relationship is shown to be a repetition of the mother's relationship with her own mother.

Other authors lay stress upon the sexual problems of these children, upon their castration anxiety and masturbation guilt (7, 10). The transmission of anxiety from parent to child is studied in detail by Eisenberg (3, 4). Many of these authors describe isolated cases in which the parents are depressed, but little emphasis is placed upon this finding (2, 11, 6).

OBSERVATIONS ON SEVEN CASES OF SCHOOL PHOBIA

Seven cases of school phobia presenting at the medical outdoor department of The

¹ From the Department of Psychiatry, The Montreal Children's Hospital; under the supervision of Taylor Statten, M.D., Associate Professor of Psychiatry, McGill University; Director of Child Psychiatric Service, The Montreal Children's Hospital, Montreal, Que.

Montreal Children's Hospital have been studied in detail, with investigation of the psychopathology of the family members. The criterion for selection of the cases studied was that the child expressed fear of school or some part of the school situation or showed inability to go to school. The series comprised 3 girls aged 12, 9, and 6 years, and 4 boys aged 9½, 9, 8, and 6 years.

The symptoms shown by the children may be divided into: 1. Openly expressed fear of going to school; 2. Depressive or manic symptoms; 3. Somatic complaints; 4. Other fears and paranoid features. All showed fear of going to school, mainly a diffuse type of fear involving all aspects of school although in one case the fear was at first limited to a particular child who had threatened to "get the patient" some 6 months before the occurrence of the phobia. Depressive symptoms were shown by 6 of the 7 children. The most common, occurring in 6 cases was frequent outbursts of weeping coming on for no apparent reason, in a previously happy child, together with a great deal of unhappy miserable whining behaviour. Three manifested both fear of dying and the wish to die, and one made several suicidal gestures. The remaining case showed little evidence of depression except when talking about his father who had deserted the family, but instead was markedly overcheerful in an inappropriate manner, his mother describing several attacks of hyperactive behaviour in which he tore things up, smashed furniture, and became incoherent, necessitating intramuscular sedation to stop him. These attacks appear to be of the hypomanic variety. Somatic symptoms were described in 5 cases, consisting of stomach cramps occurring before going to school during the weekdays and not at weekends, as well as nausea, vomiting, and headaches. Other fears noted were "fear of the dark," "fear of things under the bed," "fear of ghosts," occurring in 3 of the cases, merging rather indistinctly, since most of these fears were of being attacked, into more paranoid ideas of being kidnapped or having their food poisoned, which occurred in 2 cases.

It is suggested that these children show a syndrome comprising depressive anxiety,

mania, somatic complaints, phobia, and paranoid ideation, similar to Statten's (9) descriptions of cases of homesickness and Campbell's (1) descriptions of milder cases of affective disorders in childhood. This syndrome is close phenomenologically to the depressive disorders of adults.

Considering the psychopathology of the parents, it was found that 6 of the 7 mothers showed signs of overt depression at the time of initial consultation, and continued to show these signs for many weeks. There was, however, a marked tendency to deny these feelings of sadness; in one instance, for example, the mother came to each interview with tear-filled eyes and a depressive facies, but maintained that "she felt just fine." In 3 of these mothers the depression had definitely antedated the child's phobia, from a few days to several months, while in the others the child's symptoms had occurred before the onset of mother's depression. The most common complaints, usually made in response to the question "how do you feel" and made by 5 of these women, were anxiety, feelings of sadness or depression, weeping spells, and various somatic complaints. In several cases the complaints, apart from the fear of school, mirrored the complaints of their children, yet only 2 mothers had sought psychiatric help for themselves before bringing the child for treatment. Five had suffered from more than one depressive episode, and 3 had been depressed following the birth of the affected child, depressions which appeared to be reactive to some domestic event. In the case of the one mother who was not depressed at the first visit to hospital it was discovered that she had suffered a depressive episode lasting several months, a few years previously, and that her husband was being treated for a work phobia, depression, and cancer phobia, again almost the exact symptoms which the child manifested.

Of the fathers in this series, 3 were subject to bouts of alcoholism clearly associated with the onset of depressive feelings, most typically feelings of being worthless and inadequate, together with clear cut depressive affect. One had been hospitalized on several occasions for psychotic depressive episodes. Three others appeared

parents, and child individuals who were not considered for their families, while the severely depressed the family and was not seen for evaluation.

THE DEPRESSIVE CONSTELLATION

From the above observations and from observations made while conducting family interviews there emerges a pattern of family interaction which might be called the depressive constellation. The main features of this constellation are a tendency towards depression in the mother with similar pathology in the child and some pathology or circumstance in the father preventing him from fulfilling the paternal role in an adequate way. This may be depression or some characterological weakness with tendencies towards passivity or occasionally merely the lack of ability to provide enough maternal support for the family. When any stress occurs either from within the family or from outside the brunt tends to fall upon the mother due to the ineptitudes of her husband. At this time there is reactivation of her depressive anxieties. A specific reaction now occurs, a reaction which has often recurred at intervals from the earliest days of the particular child; she tends to develop a close relationship with him, the characteristic feature of which is her tendency towards babying or regression of the child. It is at this point that most commonly the depressive anxieties of the child are aroused. The situation may of course occur in reverse; the child may be the first member of the family to become depressed, again stimulating the regressive relationship and eventually stimulating depression in his mother. Less commonly either of these sequences may involve the father or some other family member such as grandmother with the same outcome. Gross examples of the regressive relationship were encountered in this series of cases, thus one girl had received her nightly bottle until she was 6 years old; another boy of 8 years was still wiped by his mother after going to the toilet. In addition many more subtly expressed examples were discovered.

A characteristic of these parents is their inability to tolerate and resolve depressive feelings and their tendency to avoid and minimize these and other painful affects or

painful reality experienced either by themselves or by other members of their family. When one of their children is faced with some painful feeling or aspect of reality they shield him from it by means of denial and evasion thus preventing him from learning how to cope with such circumstances. An instance of this is the many innocuities that these mothers make to keep their children out of school, usually unconscious innocuities in spite of therapeutic efforts to the contrary, which have been detailed by practically every author on school phobia. Another occurrence in the parent-child relationship is the transmission often by casual comment associated with a massive feeling tone, of depressive rumination from parent to child. Thus the comments of one depressed grandmother who was afraid to leave the house about the number of kidnappers about, was built and elaborated by one child into fantasies about the dangers of the world; he would watch carefully in case he was being followed and so on. In this way the child's sense of reality is again damaged, for his own fantasies are confirmed by those of his parents.

These aspects of the parent-child relationship, namely the regressive relationship, the mutual avoidance of painful feeling and reality, and the transmission of depressive ruminations appear in certain cases to have quite serious consequences for the psychic maturation of the child. In particular, reality testing is damaged and it is postulated that a greater liability to use projective mechanisms, thus developing paranoid states, may occur in later years.

DISCUSSION

Thus far it has been demonstrated that the school phobic child and one or both of his parents exhibit a great many features of the psychopathology of depression. It has also been suggested that the central problem in these individuals is their incapacity to tolerate and resolve depressive feelings, with a resultant return to the use of projective mechanisms leading to paranoid ideation, the development of manic symptoms, or of psychosomatic disorders, and the liability to recurrent depressive episodes. Furthermore there is a recognizable family situation which has been

and the depressive constellation which is to be seen in many other situations than that of school phobia.

It has been indicated by many workers in school phobia that the various pathological patterns of behaviour described can be seen in generation after generation. Talbot writes of the "inbred family constellation" (11) pointing out how frequently these families live in close contact with their own parents and how various problems are seen in grandmother, mother and child. Since it has been demonstrated that the psychopathology of the parents is depressive, it would be reasonable to suppose that the involved children will continue to exhibit the same pathology in their adult lives. It is very possible that there are constitutional factors involved, since it has been shown that there is a constitutional factor in depressive disorders, a predisposition which may be awakened by the family disorder described, producing the depressed infant, child, adolescent, or adult.

A number of hypotheses may now be stated:

1. That the basis of school phobia is depressive anxiety.

2. That there is a typical recognisable family constellation in this disorder which is common to many of the depressive disorders of childhood. (At present many of these disorders are not recognised as depressive in nature).

3. That this syndrome is part of the natural history of the depressive disorders.

The first two propositions can be tested by detailed examination of a larger series of school phobia cases; one of the defects of the present series is the absence of cases in the older age group, which may not conform to the syndrome detailed in this paper. The second proposition can be further tested by collecting a series of families showing the depressive constellation but in which the child presents a different clinical picture. This will enlarge our

knowledge of childhood depression. The third proposition can be tested by follow-up studies, over a long period of time, of cases of school phobia and families showing the depressive constellation, and also by retrospective studies in adults.

SUMMARY

The thesis put forward in this paper is that school phobia is part of the natural history of the depressive disorders, and is but one of the modes of presentation of such disorders in childhood. A family constellation, the depressive constellation, has been described as typical for these cases and it is suspected that this type of family will be found in many of the other modes of presentation of depression in childhood. Suggestions have been made by which the propositions put forward may be checked and expanded.

THE SIGNIFICANCE OF A DICHOTOMY IN CLINICAL PSYCHIATRIC CLASSIFICATION

G. LANGFELDT, M.D.¹

In leading psychiatric circles the usefulness of a dichotomy in clinical psychiatry is generally recognized. As we do not know the real causes for several psychiatric disorders it must be admitted that a differentiation between what we know and what we do not know should be evaluated and used for diagnostic purposes. This is not to say, however, that the dichotomy itself is the actually changing classification of psychiatric disorders.

It has always been the purpose of the international classification to arrange this according to the aetiology of the disorders generally agreed upon. No disagreement exists, I suppose, as to the value of this principle, although there will always be deviating conceptions as to what in this respect has been established. Nor do I think that much disagreement exists as to the aim of basing psychiatric diagnoses as much as possible on scientifically verified aetiological data. At any rate the usefulness of dichotomy for this purpose has been evident in the past. It is sufficient to remember the significance of the dichotomy between organic and non-organic psychiatric disorders, which makes it possible among other things to differentiate clearly between general paresis and neuritis. Another dichotomy of significance in clinical psychiatry was that between genetic and non-genetic disorders. Thus genetic studies have made it possible to group Huntington's chorea and manic-depressive psychoses as predominantly genetically conditioned disorders. It has also made it clear that at any rate some of the disorders diagnosed as schizophrenia are associated with a hereditary predisposition. However, later experiences speak in favour of not labelling these disorders as genetic in contradistinction to non-genetic but as predominantly endogenic as opposed to predominantly non-genetic disorders

(such as the psychogenic, organic, toxic and traumatic disorders). The term "predominantly endogenic" might also be used for the disorders which are predominantly conditioned by exogenous factors. Contradiction is in fact constantly evident in the clinical material of genetic and non-genetic disorders. Contradictions appearing during the first years of childhood in the sense of the interaction between the hereditary disposition and the environmental influences. It should however be noted that the term "predominantly endogenic" does not mean that a disorder has been caused by the environment or by exogenous factors, but that the disorder is predominantly conditioned by exogenous factors. Contradictions will be found directly by Hirschfeld.

The advantage in clinical diagnosis is found in the distinction between the reaction types which are constitutional and non-constitutional. It is not to be understood that the distinction between the reaction types is a contradiction between the predominantly endogenic and non-endogenic disorders. I do not restrict myself to pointing out the importance of a differentiation of these reaction types predominantly caused by exogenous constitutional types in contradistinction to those predominantly caused by exogenous constitutional or by intrapsychic dynamic factors. I shall here only mention that the constitutional types most frequently met with in clinical psychiatry are the compulsive character type, the hysterical, the paranoid, the paranoiac and the sensitive character type. All of these tend to constitute quite special reaction types. These are characterized by an excess of pre-existing character traits and in sharp contrast to the conditions in the conflict neuroses—are not conditioned in special intrapsychic procedures. The significance of a dichotomy between reaction types caused by a constitutional predisposition and those caused by exogenic or intrapsychic factors is to be found in the clinical experience that the constitutional reaction

¹ Professor of Psychiatry at the University of Oslo, Norway and director of the University Psychiatric Clinic, Oslo.

types are frequently seen to repeat themselves by rather small exogenic stimuli and that they are only little influenced by psychotherapy. This is the opposite of the conditions in psychogenic disorders in which there is a much better outlook for a definitive cure by psychotherapy.

Here, in relation to the constitutional reaction types we are not dealing with a dichotomy based on verified *aetiological* factors, as was the case with the endogenic psychoses. However, several studies concerned with characterology, and with hereditary traits as well as with habitual offenders point strongly in the direction of a hereditary disposition, even though this—as against the conditions in endogenic psychoses—does not seem to be specific. It is above all the *clinical studies* of the personality types in question and of the course of the reaction types mentioned (as shown by individual follow-up investigations) that have convinced me of the significance of a dichotomy in this field of classification.

In addition to the significance of a dichotomy of diagnostic groups (endogenic, constitutional, organic) I would like also to mention that more and more experienced psychiatrists admit the advantage of operating with a dichotomy within the different groups themselves. As to the groups usually diagnosed as *neuroses*, many psychiatrists, in Europe at least, find a great advantage in differentiating between neuroses and psychopathies. Even if the many heredity investigations (especially from the Munich school, Rüdin a.o.) do not prove the existence of *specific* hereditary constitutions, there is much evidence of typical differences between the groups mentioned. The advantage of differentiating the psychopathic (i.e. constitutional types) from the non-psychopathic (i.e. the psychogenic, and neurotic) types is previously mentioned. Let me at this point focus attention on the significance of a dichotomy within the group of neuroses, even when the psychopaths have been eliminated from it. What is then diagnosed as neuroses might be divided with advantage into 2 groups, viz.: the group of real psychoneuroses, characterized by intrapsychic conflicts, and all the other types of neuroses in which

many aetiological factors may be considered (neurasthenia, vegetative neuroses, some psychosomatic disorders etc.). The significance of such a dichotomy lies in the first place in the fact that it is predominantly in the group of the real conflict-neuroses that a therapy based on deep psychology is indicated.

From clinical points of view also there is reason to make differentiations within some of the constitutional reaction types. Thus a differentiation between paranoiac and paranoid reaction types may be of significance especially in the prognostic aspect. (The paranoiac reaction types correspond mostly to the states previously described as paranoia, while the paranoid reaction types are met with in almost all psychiatric disorders). The author has also been much concerned with the significance of a differentiation between the typical compulsive character type (corresponding to Freuds' anal erotic type) and all the other compulsive neuroses. The compulsive character type is, among other things, very little influenced by therapy, while in the usual compulsive neuroses the chance of cure is much better. Similar experiences are met with as to the difference between the typical hysterical character types and usual hysterical reaction types more psychogenically conditioned.

Let me as a last point repeat what I have been advocating for more than 20 years, viz. the dichotomy of the term schizophrenia. Based on the fact, stated primarily by Meduna, that there was a significance difference in symptomatology of cases cured by cardiazol treatment and those not cured, although both categories were diagnosed as schizophrenia, I proposed in 1937(2) to differentiate between the real schizophrenias, as a rule with a poor prognosis, and all the others which I proposed to diagnose as schizophreniform psychoses. Little by little as the symptoms of the real schizophrenia group became the object of more detailed studies and as it came out in different statistics that in fact there was a correlation between special symptoms in the initial states and the outcome after different treatments, the interest in a dichotomy became greater. Here I shall only point out the fact that Bellak(3),

is a result of his comprehensive study of the different conceptions on the problem, proposed a dichotomy between the central group of schizophrenias, which he proposed should be given the name *dementia praecox*, and all the others which he proposed should be diagnosed as schizophrenia. Rümke (4) also has contributed many well reasoned studies to the question and is much interested in a dichotomy. At the 2nd International Congress of Psychiatry in Zürich 1957, several speakers were in favour of a dichotomy between schizophrenia and schizophreniform disorders. It is of great interest that also H. Ey (5) on the basis of individual follow-up investigations has arrived at very similar conclusions. Ey differentiates between 5 forms of schizophrenia. The two first forms (the severe forms (Kraepelin types) and the medium forms (Bleuler type with chronic autistic disintegration and typical defect) are as Ey writes, "in effect the cases which, I think, all psychiatrists would be unanimous in designating as "true schizophrenias." They also correspond strictly to what I call process-schizophrenias, which in accordance with the results of Ey, I also have found regularly, to run an unfavourable course. The 3 other types of Ey (delusional marginal forms, without marked disintegration, marginal schizoneurotic forms (pseudoschizophrenic neuroses) and acute or cyclic forms) correspond fairly well to what I have proposed to call schizophreniform psychoses. So Ey's investigations, which like those from the University Psychiatric Clinic of Oslo, are based on individual followup investigations, strongly support the claim for a dichotomy of the schizophrenia group. Such a dichotomy is the only way in which international comparative psychiatry in this field can be of real, scientific value. The dichotomy is also of great significance in teaching students the prognosis and treatment of the different subgroups of schizophrenia.

SUMMARY

I wish to stress the fact that it has always been the differentiation of aetio-logically different psychiatric syndromes, that has made useful psychiatric classification possible by providing clear descriptions of inherent characteristics. However, as there are several psychiatric disorders the causes of which are still unknown clinical experience calls urgently for a classification of psychiatric groups that have several common traits in respect to symptomatology, course and treatment. Such a systematization might be of great significance to research into prognostication and treatment of the individual case. As team work from our clinic (6) has shown, it is possible even in the initial stage of a case of schizophrenia to predict the course with a certainty of more than 90%. In addition it is also possible in the initial stage to indicate which of the modern treatments has the best chance of success. Consequently if the significance of the dichotomy in psychiatry were generally accepted it would probably mean a great advantage in international comparative psychiatry.

THE OUTCOME OF SCHOOL PHOBIA : A FOLLOW-UP STUDY BASED ON 41 CASES ¹

ALEJANDRO RODRIGUEZ, M.D.,² MARIA RODRIGUEZ,
AND LEON EISENBERG, M.D. ³

This paper will describe the academic and social adjustment of 41 children with school phobia at a mean (and median) interval of 3 years following their initial clinic contact. The results on this group, to our knowledge the largest reported with this long a followup, are presented in validation of a therapeutic method which emphasizes prompt return of the child to school as the key to successful treatment.

REVIEW OF THE LITERATURE

School phobia may be defined phenomenologically as partial or total inability to go to school that, on the surface, seems to result from dread of some aspect of the school situation. It is accompanied by the signs and symptoms of anxiety when school attendance is imminent. Physiologic manifestations may be the most prominent features and may take the form of anorexia, nausea, syncope, malaise or even recurrent low grade fever. The overt expression of fear of school may be totally lacking but may be inferred from the correlation of symptoms with school days and their absence on weekends and holidays. If the child is able to put his fear into words, he may ascribe it to a particular teacher, his classmates or the dread of failing. But changes of class, course or school are strikingly ineffective in altering the syndrome.

As Johnson and her coworkers(1) were the first to suggest, the basic difficulty is not in going to school, but rather in leaving home; that is, anxiety about separation from the family. In a report to the 113th annual meeting of this Association, one of

the authors of this paper(2) described observations of children with school phobia and their mothers, which provided further validation for this hypothesis. It was evident that the separation problem was bilateral; the involved parent (usually the mother) initiated and reciprocated the child's anxiety. Observation of the child's symptoms *in statu nascendi* revealed that they were a response to the contradictory verbal and behavioral cues provided by his parents. This resulted in a direct communication of anxiety between the principal actors in the family drama. As a therapeutic corollary to this theory of symptom genesis, it was suggested that the treatment program should be centered about firm insistence on early return to school.

This represents a rather sharp deviation from traditional methods of treatment which tend to emphasize insight before action. There appear at present to be two major trends in the treatment of school phobia. Certain workers(1, 3-6) stress the desirability of removing pressure for attendance, then a period of working through of dynamic issues, to be followed by a planned return when the child is "ready." Others (2, 7-11) emphasize the importance of an insistence upon early return to school, after an initial psychiatric evaluation, to be followed by concurrent therapy while the child continues to attend. We have not hesitated to invoke the legal authority of the school to compel attendance when no real movement toward return to school was evident on the part of the family.

In objection to the latter point of view, it has been argued that recurrence or substitution of symptoms may occur, in view of the obvious diminution in the motivation for prolonged treatment once return to school has been accomplished, with the consequent likelihood of premature termination of clinic visits. It was therefore of interest to examine the outcome of the cases that had been treated by this method.

¹ Read at the annual meeting of The American Psychiatric Association, Philadelphia, Pa., April 27-May 1, 1959.

² Instructor in Psychiatry, Johns Hopkins Univ. School of Medicine, Baltimore, Md.

³ Associate Professor of Psychiatry and Pediatrics, The Johns Hopkins University School of Medicine, and The Children's Psychiatric Service, Harriet Lane Home, The Johns Hopkins Hospital, Baltimore, Md.

Our search of the literature has revealed only two large series of cases followed for appreciable periods after the termination of treatment. Waldfogel and his coworkers (8) followed a group of 36 patients for a period of 6 to 18 months. Twenty of these children were treated briefly with an emphasis similar to our own in a school setting. Eighteen continued to attend without recurrence of symptoms and two had but brief flurries of anxiety. The authors found no evidence of symptom displacement. This outcome was contrasted with 11 cases, in 7 of which treatment was refused by parents, and in 4 of which treatment was unavailable. Of these 11, only 3 had been able to resume full attendance. Glaser (11), in a report of 38 cases treated with an emphasis on early return to school, noted that 36 were in regular attendance, of whom only 3 had major persisting psychiatric symptoms, after a followup period of 1 to 2 years.

CLINICAL MATERIAL

The cases studied in the present investigation include all of the children with school phobia seen at the Children's Psychiatric Service between 1952 and 1957, 41 in all.⁴

Of this group, 14 were girls and 27 boys. In other reports (4, 7), girls have been as common as, if not more common than, boys (8). It is of interest to note the I.Q. distribution (Table 1).

TABLE 1
I. Q. DISTRIBUTION IN 41 CASES
OF SCHOOL PHOBIA

85-89	3
90-99	5
100-109	13
110-119	7
120-129	10
over 130	3
Total	41

These children with school phobia were above average in academic capability as a group. Not one patient tested below the dull normal range and half fell into the

bright to superior levels of intelligence.

Table 2 lists the age distribution of the patients.

TABLE 2
AGE DISTRIBUTION OF 41 CASES
OF SCHOOL PHOBIA

Age Range	Number of Cases
5-7	9
8-10	15
11-13	11
Total	41

Twenty-seven of the patients were 5 to 10 years of age; 14 were 11 to 13. We call attention to this age distribution as an important factor in outcome, an observation previously noted (7, 8).

The predominant short term emphasis of the treatment program is evident from Table 3.

TABLE 3
DISTRIBUTION OF 41 CASES OF SCHOOL PHOBIA
BY AMOUNT OF TREATMENT RECEIVED

Clinic Visits	Number of Cases
5 or less	18
6 to 12	14
13 or more	9
Total	41

Three quarters of the cases were in treatment for less than 4 months; only one-sixth were treated for as long as 6 months.

METHOD OF STUDY

The 41 cases upon which this report is based constitute the total population of children with school phobia seen at our clinic from 1952 through 1957. An effort was made to establish contact with the family and the school of each child. By telephone and mail inquiry, information was sought on the attendance record, school achievement and social adjustment of each patient. Information was obtained from both sources in about 90% of the cases, but from at least one source for all cases. In the 5 cases in which the family had moved out of state, the followup period is listed as of the last information available to us. It should be noted that the children themselves were not reexamined. Our data are based upon family and school reports and

⁴ Ten of these cases were included in a previous study (7); 31 have never before been reported.

must be reviewed with this limitation upon their completeness in mind.

The duration of the followup period is presented in Table 4.

TABLE 4
DURATION OF FOLLOW-UP IN 41 CASES
OF SCHOOL PHOBIA

<i>Period</i>	<i>Number of Cases</i>
15-23 months	12
24-35 months	9
36-47 months	9
48-80 months	11
	—
Total	41
(Mean duration equals 3 years)	

No case was followed for less than 15 months; three quarters were reevaluated after at least 2 years and half after at least 3 years.

RESULTS

Let us focus, to begin with, upon the record of school attendance, which we consider the primary measure of success. Outcome was considered successful only if the child was attending school regularly. By this criterion, 29 (71%) of the 41 cases were successful.

When outcome was examined separately for boys and girls, we found that 93% of the 14 girls but only 60% of the 27 boys were "successes." However, the apparent sex differential seemed largely ascribable to the age distribution of the boys and girls rather than to the sex of the patients.

When the cases were divided into two

groups, less than 11 years of age and 11 and older, a marked differential in outcome appeared. Of the 27 children younger than 11, 89% had a successful outcome; indeed, two of the three failures represented, not a lack of response to an adequate trial of treatment, but the result of injudicious medical management. It is noteworthy that once the child had attended school regularly for as long as a month, further problems in attendance arose in only two. In contrast with this excellent record, only 36% of the 14 children 11 or older were able to return to school.

When this age criterion was applied to the boys and girls separately, it accounted for the major part of the apparent sex differential, as is evident in Table 5.

Having established the patterns of school attendance, we then addressed ourselves to the over-all adjustment of the youngsters who were attending school regularly. Was it possible that other major functional disorders had been substituted for the school phobia? On the basis of the replies from schools and families, we can state that 23 of the 29 successful cases were reported to be making satisfactory academic and social progress at an average interval of 3 years after the onset of their treatment experience. The problems described in the remaining 6 patients centered about aggressive behavior disorders in 3 and academic failure in 3 (of whom 2 had I.Q.'s less than 90). It should be noted that our followup method is likely to have registered

TABLE 5
OUTCOME OF 41 CASES OF SCHOOL PHOBIA

the presence of major maladjustments only. It seems significant, nonetheless, that functional impairment from phobic or anxious behavior was not described in any of the 29 successful cases.

We attempted to identify the major factors in the therapeutic failure of the 12 children who did not return to school. Although a number of issues were involved in every case, Table 6 represents an effort to assign a primary cause for the poor outcome in each.

TABLE 6	
PRIMARY FACTORS IN THE POOR OUTCOME IN 12 CASES OF SCHOOL PHOBIA	
<i>Factor</i>	<i>Number of Cases</i>
Schizophrenia	3
Family Decompensation	4
Inadequate Treatment	3
Medical Mismanagement	2
	12

As a group, these patients were more disturbed than those who had been able to resume school attendance; 3, and possibly 4, were ambulatory schizophrenics as contrasted with none in the successful group. They came from seriously disturbed families; 4 had a psychotic parent in the home and 3 a totally inadequate father. Five of the families were characterized by neurotic interaction, not too dissimilar from the successful group, but 7 fell into the so-called multiple-problem family category. Efforts by our clinic, the schools, and other social agencies were unavailing in the search for a point at which therapeutic leverage could be applied in these families.

However, in 2 of the 5 neurotic families in which we believe a successful outcome might have been achieved, the parents broke off clinic contacts and obtained physicians' statements that the children were "too nervous" to attend school and required home teaching. Once this new family equilibrium had been established, the parents were able to utilize the medical certificates to defeat all efforts of the school authorities to require attendance. In 3 cases, it is our impression that the poor outcome resulted from a failure to establish satisfactory liaison between the clinic and the school. For a variety of reasons in each

case, the patient failed to receive sustained attention. As we reappraised the total record, it was evident that no consistent program had been carried out and that the patient and family had not had the benefit of an adequate trial of treatment.

DISCUSSION

This series of cases confirms the observation previously reported on the basis of a smaller group(7) that the prognosis is much graver for the older child with school phobia. It is a well recognized principle in child psychiatry that the significance of a particular symptom varies according to the age of the patient(12). What may be physiologic at an early age, and of dubious meaning at an intermediate period, is indicative of pathology at a later age; consider, for example, enuresis, thumb-sucking, belief in fantasy(13), and so on. In similar fashion, separation problems, while evidence of inadequately resolved family issues in the child of 6 or 7, do not portend the same degree of illness as they do in the child of 11 or 12. This is confirmed by the finding of much more serious pathology in the older children with school phobia and in their families, than was evident in the younger group. We are convinced that our efforts would have been successful in all but one of the 27 children under 11, had not misguided medical intervention by other physicians removed 2 of the cases from further treatment. On the other hand, even if we suppose that the 3 cases, whose failure we ascribe to inadequate treatment, had been given proper care and had responded to it, the salvage rate in the 14 cases older than 10 would not have exceeded 50%.

It seems clear that school phobia is not a disease entity but a symptom complex; it may be a manifestation of a situational reaction at one end of the spectrum and of a severely neurotic or even psychotic pattern at the other. This points to the importance of an adequate diagnostic evaluation as the first step in treatment. Only on the basis of such a study can an appropriate treatment plan be formulated. The therapeutic program requires close collaboration between school and clinic(7).

In our early experience with school

phobia, we were somewhat hesitant to apply pressure for prompt return to school. It became clear that we were sharing and indeed reinforcing family anxieties by our hesitance. As the feared untoward reactions failed to occur, we became increasingly aware of the considerable therapeutic value of the insistence on early return itself. To begin with, it brings into sharp focus the primary issue of separation and dissociates the therapist from the family's displacement on to fantasied dangers in the school situation. Secondly, it emphasizes our recognition of the core of health in the child; the fact that we *act* upon this premise constitutes effective reassurance to a panic-stricken family. A deemphasis on school attendance and a plan for prolonged therapy tend to signify to the family that the physician, too, is uncertain and regards the child as being as sick as they do, despite verbal formulations to the contrary. Finally, the return to school restores the child to a growth-promoting environment and removes him from his immersion in the cycle of mutually reinforced anxieties in the home.

All who have worked with cases of school phobia agree on the importance of prompt intervention. We disregard the waiting list in assigning intake appointments to such referrals on a semi-emergency basis. The longer the absence from school, the more entrenched become the original anxieties and the greater the strength of secondary fears about missed school work, the reaction of classmates, and so on. However, in reviewing our cases, we were not able to demonstrate a correlation between the duration of the school phobia and the ultimate outcome. We were gratified to find a number of cases out of school for as long as 3 to 6 months who were successfully returned. The unsuccessful cases, however, presented a considerably longer history of emotional maladjustment before they were brought to treatment.

SUMMARY

A clinical study of 41 cases of school phobia confirmed the hypothesis that this

syndrome is a variant of separation anxiety; the basic issue proved to be leaving home, not going to school. The outcome of these cases after a mean period of 3 years confirmed the utility of a treatment program of brief psychotherapy centered about prompt return to school. Therapeutic success was shown to vary inversely with the age of the child and the severity of his psychopathology.

School phobia constitutes a symptom complex which may be a manifestation of a readily reversible situational reaction or of a severely neurotic or even psychotic adjustment. Effective treatment should be based on a careful diagnostic formulation. But, with the sole exception of the overtly psychotic child, the central focus of the treatment program for all cases should be placed upon firm insistence on early return to school, reinforced by appropriate sanctions of authority.

CLINICAL NOTES

SPINAL FLUID CHANGES IN PATIENTS TREATED WITH ATARACTIC DRUGS

H. A. DENZEL, M.D.¹

The powerful behavioral changes induced by ataractic drugs are well known. The physical correlate, however, still appears to be obscure. EEG changes have been reported; and recently, Smith(1) called attention to the fact that drug-induced Parkinsonism may be accompanied by increase in spinal fluid protein. On the other hand, Bruetsch(2) reported increased protein in schizophrenic patients not receiving any drugs.

METHOD

Twenty-five patients (mainly schizophrenics) were chosen at random from those receiving either chlorpromazine or trifluorpromazine, and cerebrospinal fluid was obtained by lumbar puncture. None of these patients had ever had a positive serology in blood or spinal fluid or any detectable neurologic disease. Twenty-five mental patients not receiving any ataractic medication and without apparent neurologic disease served as controls. In those patients who had abnormal spinal fluid changes, a second specimen was obtained one week after discontinuation of drug therapy, and, if possible, a third test was done 3 weeks after the medication was stopped. Also the relationship of these findings to the incidence of Parkinsonism was investigated.

RESULTS

There was no essential difference between the findings in the patients on ataractic therapy and the control group. In the ataractic therapy group, 6 patients

had increased protein* (above 45 mg.) and the mean protein value of the whole group was 44.8 mg. In the control group on the other hand, 8 patients had increased protein with a mean value of 37.2 mg. Abnormal gold curves were found in 5 cases of the ataractic therapy group and in 6 cases of the control group. Repeat spinal fluid examinations after patients were taken off medication revealed no positive correlation between the observed changes and the drug withdrawal. Cell counts were normal in all 50 patients. The incidence of Parkinsonism did not appear to be related to the abnormal spinal fluid findings as only one patient had symptoms of Parkinsonism of that group.

SUMMARY

In a series of 25 patients on ataractic therapy and 25 other mental patients as controls, there was no essential difference in the incidence of increased protein or abnormal gold curves. The high incidence of abnormal findings in both of these groups, however, points to the possibility that these abnormal findings are unspecific and may also be found to a certain extent within the general healthy population. This study does not support the assumption that increased spinal fluid protein and abnormal gold curves are the result of ataractic therapy.

A NEW QUANTITATIVE SERUM BROMIDE DETERMINATION

GEORGE H. REYE, M.D.¹

Following the development of the qualitative urine bromide test(1) reported from Northern State Hospital in the American Journal of Psychiatry of August 1959, it was decided to attempt a quantitative serum determination. Preliminary investigation demonstrated it to be both simple and feasible.² The determination is dependent upon the oxidation of the bromide ion to free bromine and the intensity of bromine's inherent color is measured spectrophotoelectrically. Chemically the reaction is: $\text{NaBrO}_3 + 6\text{HCl} \rightarrow 3\text{Br}_2 + 3\text{H}_2\text{O} + 6\text{NaCl}$.

This procedure can be routinely performed by the average clinical laboratory and has the merit of following Beer's Law from a serum equivalent bromide concentration of 25 mg.% through 1000 mg.%.

The routine serum bromide determination as used by most clinical laboratories is that of Wuth(2) which follows Beer's Law to about 220 mg.%. Modifications of this test in order to read higher serum levels are inaccurate and according to Dr. Compton(3), the Wuth method is "wholly unreliable for values over 300 mg.%" In our laboratory modifications of the Wuth determination necessary to read known bromide concentrations, equivalent to serum levels of 500 to 1000 mg.%, has resulted in errors of the magnitude of 200 mg.%.

Reports of case histories with serum bromide levels well over 1000 mg.% as determined by a modified Wuth method continue to appear in current literature, despite authoritative opinion(3) that such levels are incompatible with life.

MATERIALS AND METHODS

Reagents:

1. 10% trichloroacetic acid: Ten grams of trichloroacetic acid are dissolved in 100 ml. of distilled water.

¹ Director of Research, Northern State Hospital, Sedro Woolley, Wash.

² The author wishes to express his appreciation to Dr. C. H. Jones, Superintendent, and Dr. J. Joffe, Chief of Medicine, for making this study possible and for their suggestions and criticisms. The technical assistance of David Higgins and William Robinson is gratefully acknowledged.

2. 5% sodium or potassium bromate: 5 grams of the bromate are dissolved in 100 ml. of distilled water.

Procedure:

1. A protein free filtrate is prepared by mixing 1 ml. of serum and 9 ml. of 10% trichloroacetic acid and then filtering through No. 42 Whatman filter paper.
2. 5 ml. of the clear filtrate is pipetted into a photometer cuvette which will represent the unknown, and 5 ml. of 10% trichloroacetic acid is pipetted into another cuvette which will represent the reagent blank.
3. To both cuvettes, 1 ml. of 5% KBrO_3 is added and the contents mixed.
4. Several drops of mineral oil then are added immediately to the unknown cuvette without agitation to prevent loss of bromine vapor which would result in low readings.
5. Read in the spectrophotometer at 445 mμ with the reagent blank set at 100% transmittance.
6. The unknown is read as % transmission at 5 minutes after the addition of the bromate. The concentration of bromide in mg.% is then read directly from a semi-log graph or from a direct reading table abstracted from the graph and the results reported as sodium bromide.

CALIBRATION CURVE

All of the calibrations were performed on a Coleman Junior Spectrophotometer, model 6A and 19 mm. cuvettes were used throughout. A Leitz or other similar photometer possessing a 445 mμ filter could be similarly calibrated.

Standards were prepared as follows and are reproduced here in order to enable others to easily calibrate their own curve on semi-log paper. Working Standard (W.S.)—100 mg.% NaBr.

The procedure for each of the above reference standards is then exactly the same as previously outlined under procedure No. 3-6, the standard being treated as the unknown.

A semi-log graph wherein % transmission is plotted against mg.% of sodium bromide is herein reproduced. Known concentrations from 50 mg.% through 1000 mg.%, similarly diluted as in serum, were used. To be noted is the correlation with Beer's Law from 90% transmission through 16% transmission.

1959]

100 mg. of NaBr is dissolved in 100 ml. of 10% trichloroacetic acid.

To	.25	ml. of W.S.	add	4.75	ml. of 10% trichloroacetic acid	=	50 mg.%

	1.0	"	"	4.0	"	"	200 mg.%
	1.5	"	"	3.5	"	"	300 mg.%
	2.0	"	"	3.0	"	"	400 mg.%
	2.5	"	"	2.5	"	"	500 mg.%
	3.0	"	"	2.0	"	"	600 mg.%
	3.5	"	"	1.5	"	"	700 mg.%
	4.0	"	"	1.0	"	"	800 mg.%
	4.5	"	"	.5	"	"	900 mg.%
	5.0	"	"	.0	"	"	1000 mg.%

with the bromate reagent to liberate iodine. Serum equivalent concentrations of iodide, from 50 mg.% to 600 mg.%, were tested with the bromate reagent and iodine was liberated. Although the color of iodine in these concentrations duplicated that of bromine, iodine is spontaneously oxidized within 2 to 3 minutes to the colorless iodate state. This oxidation is effected by the bromate reagent.

SUMMARY

The new quantitative serum bromide determination described is dependent upon oxidation of the bromide ion to free bromine and follows Beer's Law from a serum equivalent bromide concentration of 25 mg.% through 100 mg.%.

year. Only female patients who had been incontinent, destructive, combative and who frequently disrobed were included. By February 23, 1959, exactly 4 years after the project had begun, 822 patients had

been treated. Their average age was 41, their average hospitalization 8 years. Of this number, 258 had been discharged during the 4 years and remained on chlorpromazine and reported at 3-week intervals to a special drug clinic at the hospital. For further details of the project and the functioning of the drug clinic see previous reports (1, 2, 3, 4, 5, 6).

Of the 258 discharged, 101 patients were returned to the hospital during the 4-year period. It is this group that is of special interest in this report.

Forty-two of the 101 returnees were discharged a second time, but 18 of these 42 returned once more. Six of these 18 were discharged for a third time, and they returned again. Thus, at the end of the 4-year period, 24 patients of the 101 returnees were outside the hospital after having returned and having been redischarged. Hence 77 patients of the original 258 discharged were back in the institution at the end of 4 years.

The reasons for return of the 42 patients, once or several times, as the case may be, were as follows: (a) Relapsed in spite of taking drug regularly, 24; (b) uncooperative as to taking drug, 9; (c) placebo relapse,² 1; (d) irregular clinic attendance, 4; (e) family unwilling or unable to keep patient, although no relapse occurred, 3; (f) patient herself desired to return, 1.

The average length of time away from the institution during the first discharge of these 42, was 8 months, but the 18 discharged a second time merely stayed away for an average of 5 months. The 6 who were discharged a third time returned after having been away only for a 3 months average.

Dosages of chlorpromazine during the discharge period ranged from 200 to 600 mgs. a day. After return, drug dosages were adjusted to the needs of the patient. Where

² A placebo study is being conducted parallel with other investigations on our discharged outpatients, 72 patients being involved in this group (2, 3, 4)

this did not apply, other facets of the overall treatment plan, or undetermined factors helped to bring about again clinical improvement to warrant discharge once more. As a rule, patients who relapsed due to an insufficient dosage of the drug responded within one or two weeks to an increased dosage (up to 800 mgs. a day orally).

The 42 patients who had returned and were discharged a second time, spent an average of 8 months with us between return and second discharge, while the 6 who were discharged a third time stayed in the institution before the third discharge an average of 6 months.

SUMMARY

A note of optimism is indicated regarding the future of hospital-turned tranquilizing drug patients. At the close of 4 years of an extended chlorpromazine study on once extremely disturbed mental patients, 24 of 101 returned patients were once more outside the institution. Some of these had been discharged and returned two or three times. These 24 amount to 23.7% of the total returnees. Returned tranquilizing drug patients must, therefore, not become "forgotten people," but deserve further interest and consideration.

A RAPID, SEMI-QUANTITATIVE URINE COLOR TEST FOR PIPERAZINE-LINKED PHENOTHIAZINE DRUGS (COMPazine, TRILAFON AND ANALOGUOUS COMPOUNDS)

FRED M. FORREST, M.D., IRENE S. FORREST, Ph.D., AND
AARON S. MASON, M.D.¹

Tests and reagents for phenothiazine compounds in urine and their significance in psychiatric practice were previously reported by us(1-4). The test solutions described for the detection of all urinary phenothiazine compounds in small amounts (3) and for Vesprin (triflupromazine)(4) will also reveal the presence of phenothiazine drugs coupled to a piperazine ring. However, the color development with these reagents is not sufficiently intense or gradient to permit the development of a color chart for simple and instantaneous semi-quantitative readings. Moreover, reports of side effects and toxicity in general medical and pediatric journals(5-13) seem to indicate the need for a specific and reliable test for the piperazine-linked phenothiazine compounds, especially for prochlorperazine (Compazine),^{2, 3} and perphenazine (Trilafon). The following test was devised to meet this specific requirement:

A 1/1000 molar solution of mercuric nitrate in concentrated hydrochloric acid (343 mg. $\text{Hg}(\text{NO}_3)_2 \cdot \text{H}_2\text{O}$ in 1000 ml. conc. HCl) was found to be a suitable test reagent for this class of drugs. It yields a scale of color reactions ranging from pale pink via more intense shades of pink to

light violet and finally more intense violet, for drug doses of 10 to 125 mg. per day. The reaction is extremely sensitive and is produced by a fraction of a microgram of intermediary drug metabolite contained in 1 ml. of urine, after drug doses below 100 mg. per day.

The test is performed by mixing 1 ml. of urine with 1 ml. 10% trichloroacetic acid, shaking gently, and then adding 1 ml. of the mercuric nitrate reagent to the mixture. The resulting color complexes are of limited stability, especially in the lower drug doses, and should be read against the color chart, graded from (+) to (+++), within 30 seconds. The pale pink (+) level of the color chart represents average daily drug dosage of 10 to 30 mg., the pink (++) level dosage of 30 to 70 mg., the light violet (+++)—70 to 120 mg., and the more intense violet (++++) level —120 mg. and over. (See color chart.)

The individual levels constitute average reactions compiled on the basis of approximately 500 determinations per drug and dosage level, obtained from approximately 300 different patients. A total of well over 3000 urine specimens containing Compazine or Trilafon were tested. These two drugs give the same color reactions. Limited tests with Dartal (thiopropazate), which has a very similar chemical structure, yielded the same color reactions as described above. However, representative numbers of patients on Dartal have not as yet been investigated.

Triflupromazine (Stelazine) usually prescribed in daily dosage of 6 to 40 mg. per day, conforms to the lower color intensities (+) and (++) of the color chart. However, from 3 to 6 weeks after institution of Stelazine therapy, the majority of patients will show a higher intensity level despite constant drug dosage, and violet to bluish test colors of varying intensity may be obtained in the urines of patients receiving a total daily drug dose of as little

¹ Respectively, Chief, Acute Service; Research Biochemist; and Director, Professional Services, VA Hospital, Brockton, Mass.

² Pollack, B. (Am. J. Psychiat., 115: 77, 1958) in evaluating our test 2, tried to extend it to Compazine and found it of limited usefulness for qualitative detection of 50-150 mg. daily dose.

³ Vesell, E. S. (New Engl. J. Med., 260: 1078, 1959): The claim made for a reagent consisting of 10% ferric chloride in 1% hydrochloric acid, of which 1 ml. are added to 3 ml. urine, whereby small amounts of urinary Compazine metabolite are reportedly demonstrable, could not be confirmed by us in a series of 200 urine specimens, containing the metabolites of daily doses of 10 to 15 mg. of drug. The pH of approximately 3 prevailing in this test is unsuitable for the demonstration of Compazine metabolites which call for a test pH of 1 or less, and purple color reactions obtainable at pH 3 are due to other reactants e.g. metabolites of acetylsalicylic acid.

as 24 mg. A small number of tests with SQ 4918, fluphenazine (Prolixin), seemed to follow the same pattern as would be expected in view of the close chemical relationship of these two drugs. The cause of this color shift can not be explained at present, and we are currently investigating whether this unusual reaction of the trifluomethylated derivatives of prochlorperazine and perphenazine is due to actual accumulation of the drugs in body tissues, or whether there is a shift in the ratio of drug metabolites in favor of the intermediary oxidation compounds which account for the metal color complex. In the meantime it is recommended that Stelazine and Prolixin color reactions be considered rather a qualitative means of detecting the drugs than a means of semi-quantitatively estimating the urinary drug level by this test.

RELIABILITY OF MERCURIC NITRATE TESTS

Among a number of heavy metal salts dissolved in more or less concentrated acids, which we investigated for suitability in testing for urinary phenothiazine drug metabolites, there were a number of metals, e.g. cerium, thorium, vanadium, chromium, molybdenum, tungsten, uranium and osmium—all of which may change valency and were thus potential reactants with the intermediary oxidative drug metabolites—which gave excellent and intense color reactions with individual phenothiazine drugs. For the specific group of the piperazine-linked phenothiazine compounds, however, they offered no advantage over the mercuric nitrate solution described, and were less specific in most instances, thus giving rise to a higher percentage of false positive tests.

With regard to false negative tests occurring with mercuric nitrate reagent, none have been seen in more than 3000 examinations, including control tests. During performance of the test, when 10% trichloroacetic acid is added to the urine, a white precipitate will form, if albumin is present, but the color reaction remains distinct. It is theoretically possible that single low drug doses or extremely dilute urines may give false negative tests. In such cases, the test

should be performed 1 to 3 hours after drug administration, during the peak excretion period of drug metabolites.

False positive tests were obtained in approximately 2% (9 in 500) in patients and personnel who were not on phenothiazine drugs and served as controls. Most of these were encountered in cases of impaired liver function, and seem to result from reactions between the mercuric nitrate reagent and bile metabolites. Thus a positive test should not be uncritically accepted in patients with liver abnormality, whereas a negative test is always an unequivocal indication of no recent phenothiazine intake.

The simultaneous presence of any other phenothiazine drugs will interfere with the semi-quantitative evaluation of the phenothiazine-piperazine compounds. Previous administration of other phenothiazine drugs also will interfere with the color intensities, unless at least a 3 months drug-free interval is interposed, since phenothiazine drugs are eliminated in small daily portions over a period of many weeks after discontinuation of drug therapy(4).⁴ Non-phenothiazine derived drugs such as reserpine, meprobamate, various types of energizers, barbiturates, salicylates, vitamins *etc.* do not produce color reactions with the mercuric nitrate reagent, and do not interfere with this test.

ADDENDUM

Some *in vitro* tests on control urines to which very high doses of anti-tubercular drugs such as streptomycin, paraamino salicylic acid or isonicotinic acid hydrazide plus phenothiazine drugs and their metabolites had been added, indicated potential interference with this and previously reported tests for phenothiazine drugs. However, no false positive or

⁴ An unpublished drug discontinuation study has been in progress in this hospital since Feb. 1959, on a group of chronic mental patients stabilized on long term daily doses of various phenothiazine drugs. A preliminary report was given at the Research Conference on VA Cooperative Chemotherapy Studies in Psychiatry at Memphis, May 20-22, 1959, and currently, after more than 18 weeks, 25% of the patients continue to excrete measurable amounts of drug metabolites. A full report, covering the psychiatric, clinical, psychological and biochemical data will be published at a later date.

negative tests were encountered in patients actually receiving combination therapy of anti-tubercular and phenothiazine drugs, in any ratio tested to date. The chemical aspects and clinical implications of the interference observed in vitro is being further investigated in this hospital.

STORAGE OF THE MERCURIC NITRATE REAGENT

The addition of 10% trichloroacetic acid to the urine before mixing with the mercuric nitrate reagent, reduces the acidity of the total volume of the test solution (urine plus reagent), and prevents some false positive tests. However, the 10% trichloroacetic acid can not be pre-mixed with the mercuric nitrate reagent, since aqueous or alcoholic components, or even prolonged exposure to atmospheric moisture renders the mercuric reagent ineffective for formation of the color complex with the phenothiazine drug metabolites, due to a rapidly proceeding hydration process. The mercuric nitrate reagent must therefore be stored in a tightly closed bottle.

SUMMARY

A specific urine color test for the piperazine-linked phenothiazine drugs (Compazine, Trilafon, Dartal, Stelazine, Prolixin, etc.) is reported, in which 1 ml. of urine is mixed with 1 ml. 10% trichloroacetic acid. To this mixture 1 ml. of 1/1000 molar solution of mercuric nitrate in concentrated hydrochloric acid is added. The resulting color is read within 30 seconds against a color chart showing 4 color intensities, marked from (+) to (++++), for daily drug doses from 10 to 125 mg.

The test is suitable for semi-quantitative determination of Stelazine and Prolixin for the first few weeks of administration only, and thereafter should be used as a qualitative test.

No false negative tests were encountered in over 3000 urine specimens. Two percent false positive tests seen in control specimens are tentatively ascribed to bile metabolites arising from impaired liver function. Potential errors in the interpretation of these tests in case of simultaneous or previous intake of other phenothiazine drugs are discussed.

BREVITAL ANESTHESIA IN ELECTROCEREBRAL THERAPY

EMERICK FRIEDMAN, M.D.¹

In a recent preliminary report⁽¹⁾ Brevital² was found to be an ultrashort acting intravenous anesthetic agent well suited for ambulatory electrocerebral procedures. Rapidity of action and recovery from anesthetic effects were prominent, as well as

ease of administration and freedom from complications. Within the past year, 105 patients have been given a total of 1,460 electrocerebral treatments employing Brevital as the preliminary anesthetic agent. A wide variety of electrocerebral treatments was administered. Anesthetic efficiency, ease of administration, freedom from com-

¹ 497 State St., Albany, N.Y.

² Methohexital (Lilly)

plications, compared favorably with thio-barbiturates. However, the duration of anesthesia was considerably shortened and treated patients returned home or to work from the office in less than half the time noted for other barbiturates. Minimizing the barbiturate effect was felt to have importance in evaluating this method.

Similar, ultrashort anesthetic action was found in a series of 60 trials without electro-cerebral procedures. In the latter, Brevital was employed for narcosynthetic therapy and for induction of sleep during EEG studies. In all of this work there was noted an absence of unpleasant smell-taste experience, frequently encountered with thio-barbiturates.

It was concluded that Brevital was of distinct usefulness in ambulatory electro-cerebral and in narcosynthetic therapies as well as in procedures requiring very brief anesthesia.

A satisfactory standardization for ECT work was developed. To each 500 mg. ampule of Brevital, was added 30cc. distilled water and 10cc. doses of the solution were drawn in individual syringes. Immediately before administration, atropine sulphate, 0.6 mg. and 20-30 mg. succinylcholine, in solution were added to the syringe. Injection took 10 seconds. ECT (unidirectional) with resumption of respiration was completed in 60 seconds. Awakening occurred in 3-5 minutes with the patients out of bed, ready to leave in about 15 minutes.

Prolonged electrocoma or electrostimulation at times required an additional 5-10cc. of Brevital solution (without succinylcholine) and patients would frequently awaken at the end of 3-7 minutes.

CLINICAL RESULTS WITH NIALAMIDE (NIAMID) IN CHRONIC REFRACTORY MENTAL DEPRESSIONS

FRANCIS A. GAGLIARDI, M.D.¹

Sigmund Freud is universally accepted as the father of modern psychodynamic psychiatry. However, we sometimes lose sight of the fact that he was originally an organic neurologist. It is not hard to understand, therefore, why he is reputed to have said and written that beneath the superstructure of psychoanalysis, one day we would find the workings of the psyche explainable in organic and biochemical terms. Most of us who have used electro-cerebral treatments of one type or another have come to feel that the current causes some electrochemical change in some part of the brain. Possibly the biochemists and the neurophysiologists are at the threshold of the discovery of the "magic key" that will open the portals to the unknown workings of the psyche. Some of our more enthusiastic pharmacologically-oriented psychiatrists and some pharmaceutical houses would have us believe that we have al-

ready passed beyond the threshold. However, the writer feels that we still have quite a way to go down "Chemistry Road" before we have reached the goal. Nevertheless one of the important signposts along the road is the new group of drugs called the mono-amine oxidase inhibitors and their use as antidepressants. They have been euphemistically called psychoenergizers, a term originally credited to Freud(1).

The first such drug was iproniazid. It proved to be quite successful as an antidepressant. However, iproniazid was also highly toxic, especially to the liver, and has been incriminated in several fatalities. Naturally, there has been considerable interest in finding a suitable safe replacement. Nialamide² brought to my attention as a candidate with less toxicity and equivalent potency, has been used for the past

¹ Attending Psychiatrist Mary Immaculate Hospital, Jamaica, N. Y.

² The author wishes to express his thanks to Charles Pfizer & Co. who supplied the Nialamide (Niamid) for this study.

6 months in a specially selected private group of chronic refractory depressions.

Nialamide was given to 42 chronic depressed patients that the writer was thoroughly familiar with for 1 to 12 years. All had received one or more courses of ECT, and many were on maintenance ECT for several years. The criterion for success of the drug was the discontinuance of ECT entirely or the marked diminution of ECT administration to these hard core patients. In common with many psychiatrists who have given thousands of ECT, there is a desire to substitute a less hazardous and less formidable procedure. Despite the technique as described by Impastato(2, 3), which makes the administration of ECT smooth and sophisticated as compared to the early days of "straight" ECT with resultant complications and fractures, we would rather avoid this type of treatment if an equally efficacious agent could be substituted.

This study reveals that almost 80% of the refractory patients treated were improved on nialamide alone or nialamide combined with occasional ECT. The various types of depressions included both psychotic and neurotic categories. The results show that 12 (29%) markedly improved (*i.e.* no further ECT necessary) 21 (50%) improved (*i.e.* the number of ECT was cut to at least

half because the time interval between maintenance treatments was at least doubled), and 9 (21%) were unimproved. The patients who did not respond with this drug were those classified in the agitated depressed group. The drug effect is often slow in onset, requiring about 10 or 12 days at a dose level of 75-100 mg. daily. Because of this, extreme caution should be used in depending on drug alone in highly suicidal patients.

Nialamide showed no toxicity in any patient. Side reactions were few and minor. With many types of mental depressions it would be a safe drug in the hands of the average physician. It may be used alone or in combination with ECT, chlorpromazine, meprobamate, barbiturates. The findings indicate that nialamide is a valuable addition to the group of mono-amine oxidase inhibitors commonly known as psychoenergizers, and is extremely safe and free of toxicity.

SERUM OXIDASE ACTIVITY IN CHRONIC SCHIZOPHRENICS TREATED WITH TRANQUILIZING DRUGS

LEO E. HOLLISTER, M.D.,¹ AMEDEO S. MARRAZZI, M.D.² AND
JESSE F. CASEY, M.D.³

In recent years oxidation of N, N-dimethyl-p-phenylene-diamine (DPP) by serum has been studied extensively in schizophrenic and normal populations. Originally it was thought that elevated serum oxidase activity in schizophrenics might provide a biochemical diagnostic test(1). This belief has not been substan-

tiated by a number of observers. Either no essential difference between schizophrenic and normal populations in regard to oxidase activity was found or the overlap between groups was so great that the test was valueless for individual patients(2, 3). Even in schizophrenic patients having increased serum oxidase activity, this has been explained as an artifact due to decreased ascorbic acid levels from marginal nutritional intakes(4, 5).

Regardless of whether the test has any diagnostic value, it would be of interest if

¹ Chief, Medical Service, VA Hospital, Palo Alto, Calif.

² Director, VA Research Laboratories in Neuropsychiatry, Leech Farm Road, Pittsburgh, Pa.

³ Director, Psychiatry and Neurology Service, VA, Washington, D. C.

serum oxidase activity reflected clinical changes in schizophrenics under treatment. An opportunity to study this aspect of serum oxidase activity was afforded during a large-scale cooperative study using double-blind controls(6). Chronic schizophrenics were treated with 5 phenothiazines (chlorpromazine, trifluorpromazine, prochlorperazine, perphenazine, and mepazine) and phenobarbital. Measurements of clinical status were made prior to treatment and at the end of 5 and 12 weeks of drug therapy, using the Multidimensional Scale for Rating Psychiatric Patients (MSRPP). During the course of this study measures of serum oxidase activity were obtained on 48 patients at times corresponding with the clinical evaluative measures. Most oxidase determinations followed the original Akerfeldt technique. A few were reported in which minor variations (smaller serum sample, longer incubation period, addition of buffer) were added. The distribution of cases by drug was reasonably even, 10 having received prochlorperazine, 8 trifluorpromazine, mepazine, perphenazine, and phenobarbital, and 6 chlorpromazine.

An attempt was made to correlate changes in serum oxidase activity with changes in the total morbidity score of the MSRPP. Calculations were made of the percentage change for both measures from the period of no drug treatment to the 5th and 12th weeks of treatment. A correlation was then made between the mean percentage changes of both measures. At the end of the 5th week there was no correlation at all. At the end of 12 weeks a weakly negative correlation was obtained (correlation coefficient = $-.24$) which was not significant. A further analysis of the

data was made for each of the specific drug groups. In each case serum oxidase activity was decreased by treatment with phenothiazine derivatives while slightly increased with phenobarbital. However, the differences between the mean changes between the various drug groups were not significant.

On the basis of this study it was concluded that changes in serum oxidase activity were not significantly correlated with clinical improvement in schizophrenic patients treated with phenothiazine derivatives. Such changes as were noted in serum oxidase activity tended to be contrary to expectation, that is, reduction in total morbidity was accompanied by increased oxidase activity. No specific effects on oxidase activity due to pharmacologic actions of individual drugs could be shown, though there was a tendency for the phenothiazine derivatives to decrease activity somewhat.

CASE REPORTS

TREATMENT WITH HIGH DOSAGE TRIFLUPROMAZINE

M. G. JACOBY, M.B., B.S.¹

In 1958 Jacoby(1) described a case of chronic paranoid schizophrenia of 15 years' standing who had not responded to lobotomy. She was given chlorpromazine, reaching a dose of 6,400 mg. daily to control her symptoms. This dose has now been cut to 300 mg. daily (unpublished work) without recurrence of her symptoms.

Further work(2) with phenothiazines in chronic maximally disturbed schizophrenics yielded some satisfactory results in doses of up to 10,000 mg. chlorpromazine daily and 2,000 mg. prochlorperazine daily.

Triflupromazine is a phenothiazine about three times as potent as chlorpromazine and it was decided to try its effects on a maximally disturbed chronic schizophrenic.

Case History.—G.L.G. is a colored female who was born in 1913. Her early life is said to have been normal.

In October 1950 she began to be seclusive. She became mute, resistive and refused to eat, losing 70 lbs. in weight. She was admitted to Central Islip State Hospital in June 1951 with the diagnosis of catatonic schizophrenia. She remained mute and blocked and was started on ECT in December 1951 with only temporary benefit.

In September 1952 she made a homicidal attack on an attendant, trying to strangle her. Following this she continued to be compulsively combative, manneristic, hallucinating and responding to her hallucinations. Permission for lobotomy was refused by her relatives.

In January 1955 she was started on serpasil with only slight improvement. She remained impulsively aggressive, broke windows on many occasions and made several attempts at suicide with broken glass. She stated that she heard the voice of her dead father, and tried to kill herself so that she could join him.

In February 1957 she was started on chlorpromazine, building up to a dose of 3,200 mg. daily but remained confused, disoriented and combative. In May 1957 she turned over two television sets because voices from them were

talking to her and in doing so she severely injured another patient. She was started on regressive shock(3), receiving 32 electroconvulsive treatments in 8 days.

She showed no improvement after this treatment and in August 1957 she was started on promazine, building up to a dose of 1,600 mg. daily, with no observable benefit.

In August 1957 she had several grand mal seizures (probably as a result of the ECT) but no abnormality was seen on the electroencephalogram. She was started on dilantin gr. 1½ t.i.d. because of this.

In December 1957 the patient was started on triflupromazine, gradually increasing the dose until a level of 1,000 mg. q.i.d. was attained. At this level she was in fair contact with her environment, for the first time in many years. She was friendly and sociable and her productions were coherent and spontaneous but rather fragmentary. She denied hallucinations but could sometimes be seen talking to herself and addressing non-existent people. By June 1958 she had improved sufficiently to be given parole of the hospital grounds. Her family were very satisfied with her condition and wished to take her home overnight, although in the opinion of her physician she was not yet well enough.

Table 1 shows the blood level two hours after each dose of triflupromazine. The patient weighed 80 kg. so the dose of 1,000 mg. was equivalent of 12.5 mg. triflupromazine per kg. body weight.

At no time while receiving medication at this level did she show any signs of Parkinsonism, liver damage, blood dyscrasias or hypotensive attacks.

She was maintained on 4,000 mg. triflupromazine daily until February 1959, when she accidentally set fire to herself while lighting a cigarette. This resulted in severe third degree burns, from which she died two months later. At autopsy her liver was normal.

DISCUSSION

This patient showed a response to triflupromazine in very high doses after having been refractory to all other treatment.

triflupromazine	1000mg.		1000mg.		1000mg.		1000mg.	
micrograms triflupromazine per ml plasma		3.2		2.2		1.3		1.7
triflupromazine sulfatide per ml plasma		2.3		2.0		1.5		1.5

At no time did she show any side effects.

The blood levels are probably of little value in assessing the effects of the phenothiazines. The reason for suggesting this is that certain side effects such as Parkinsonism may continue for a considerable time after the administration of the drugs has ceased, and when no apparent drug level can be found in the blood. Smith(4) states that after oral doses of 20 mgs. of triflupromazine per kg. of body weight in dogs he has been unable to find detectable levels of triflupromazine in the plasma two hours later.

It should be appreciated that there is no top level of dosage with the phenothiazines. This class of drugs should be regarded like insulin, in that the average diabetic re-

quires less than 40 units of insulin daily but the resistant case may need many hundreds.

SUMMARY

A case is presented where a dose of 4,000 mg. triflupromazine daily was required to control a chronic schizophrenic.

I wish to thank Dr. Charles I. Smith of The Squibb Institute for determining the plasma levels of triflupromazine.

HISTORICAL NOTES

DR. PLINY EARLE (1809-1892)

ERIC T. CARLSON, M.D., AND ILLIAN PETERS, A.B.^{1 2}

We celebrate this year the sesquicentennial anniversary of the birth of a great American President, Abraham Lincoln. The American Psychiatric Association can observe a similar celebration in remembering the anniversary of the birth of two of its founders: Thomas S. Kirkbride and Pliny Earle. It seems only appropriate this month to review briefly the life of Pliny Earle, who was born on December 31, 1809, in Leicester, Massachusetts, one of the 9 children of a Quaker family. From his father, young Pliny learned about manufacture, agriculture and carpentry, and thereby gained valuable experience for his later work in hospital administration. In 1826, after completing his preliminary education in Leicester, he enrolled at the Friends' School in Providence, Rhode Island. He remained there as a teacher from 1829 through 1835, being appointed principal the last year. As early as 1832 Earle began to study medicine; in 1835 he entered the University of Pennsylvania Medical School and received his degree in 1837. He decided to continue his education in Paris and combined this objective with an extensive European trip through 1837 and 1838.

Earle was well received in English Quaker circles, and here learned more about the York Retreat through his conversations with Samuel Tuke. Throughout his journey he visited various mental hospitals and met several workers in the field, including Esquirol and Leuret. It appears that his interest in psychiatry antedated his trip, for not only had a beloved cousin suffered from mental illness, but his medical school thesis dealt with insanity. He had been fascinated, moreover, watching Dr. Samuel

B. Woodward treat the patients at the Worcester State Hospital.

On his return to America in 1839 Earle opened an office for general practice in Philadelphia, but in the summer of the following year he gave up his practice in order to become resident physician at the Friends' Asylum in Frankford. He remained there until 1842; in 1844 he accepted the superintendency of the Bloomingdale Asylum in New York City. During the ensuing years he developed an excellent moral treatment program at Bloomingdale and thereby strengthened the status of the physician-superintendent. In 1849, during a period of mental depression, he again went abroad. The years following his return to America he spent in a desultory fashion. Until 1852 he lived in retirement at Leicester, but during the next two years he maintained a consultative practice in New York City and served on the board of visiting physicians to the City Lunatic Asylum on Blackwell's Island. Because of ill-health he returned to Leicester in 1854 and remained there for the next 10 years. In 1856 Dr. Charles N. Nichols, chief of St. Elizabeths Hospital, invited him to Washington, and during the Civil War, after the U. S. Sanitary Commission did not accept his proffered services in 1862, he assisted Dr. Nichols as chief of the male wing of the hospital.

Finally, in 1864, Earle assumed the management of the Northampton State Hospital in Massachusetts. Intended for chronic cases, mainly the foreign pauper insane, it had been badly—and expensively—operated previously. Earle's administrative ability, his frugality, and his love of order and discipline soon achieved a striking transformation. He instituted a dynamic activity program based on patients' labor, and the hospital ceased to be a liability to the state. It became an example (although history may not record it as the best one)

¹ Department of Psychiatry of the New York Hospital (Payne Whitney Clinic)—Cornell University Medical College, New York, N. Y.

² This investigation was supported in part by a Research Grant (M-2146) from the National Institute of Mental Health, U. S. Public Health Service.

of what economical and efficient management could accomplish. In addition to improving the hospital's administration Earle also bettered its therapeutic program: when the state instituted a boarding-out plan in 1885 most of the suitable candidates were found in Earle's hospital, evidence that many of his patients achieved virtual recovery.

Besides psychiatry, three other themes predominate in Earle's life: teaching, writing, and a liking for mathematics. He was one of the earlier teachers of psychiatry in this country; in 1853 he lectured on insanity at the College of Physicians and Surgeons in New York, while in 1863 he was appointed Professor of Psychologic Medicine at the Berkshire Medical Institute in Massachusetts.

He was apparently one of the first in America to offer a course of educational lectures to psychiatric patients, reportedly giving one while still a resident at the Friends' Asylum. It is known that he delivered an elaborate series of lectures at the Bloomingdale Hospital, treating such various subjects as: travel in Europe, physiology, electricity, chemistry, and poetry. He lectured to patients at St. Elizabeths Hospital during the Civil War, and later at Northampton he continued his illustrated course, which was attended by approximately half the patients and included 6 lectures on the brain and mental disorders.

Allied to his desire to teach was his inclination to write. Although he never obtained a reputation for literary charm he worked conscientiously from his careful study and observations. Like teaching, writing was part of the family tradition: an elder brother published a Worcester newspaper and his mother loved and composed poetry. Earle is reputed to have published poetry while he was in his teens, and in later years he submitted poems to a number of publications and corresponded with Edgar Allan Poe. Finally in 1841 his collected poems were published in a work entitled *Marathon*.

Earle's professional writings dealt mainly with psychiatry and related subjects. A portion of his graduation thesis appeared in the *American Journal of Medical Sciences*,

while his report of his visit to the European asylums was issued in 1841. Such reviews of hospital practice were to represent the bulk of his published writings. After a second trip through Europe he wrote a more extensive study treating the institutions in Prussia, Austria, and Germany. Perhaps his most famous medical article was one denouncing bloodletting, which appeared in 1854. Earle is best remembered, however, for his studies on the curability of insanity, and it was this work on which he wished to base his reputation for posterity.

His statistical bent was evident as early as 1833, when he analyzed the types of spelling errors found in his students' work. He used statistics somewhat in his graduation thesis and more extensively in his 1848 history of the Bloomingdale Asylum, in which he first pointed out that "cured" patients who relapsed were often admitted as "new" cases. He participated in assessing the U. S. census figures for 1860 and soon afterwards he induced Dr. Nichols to introduce a new form of registration at St. Elizabeths which was reportedly both exhaustive and exhausting. Through his influence similar forms were introduced into the Massachusetts system in 1880. In 1876 he initiated his campaign against the deceptive system of reporting recovery throughout the country, finally publishing his famous book on the curability of insanity in 1887. J. S. Bockoven has well pointed out the negative influence of this work and has demonstrated that Earle himself misused statistics in order to prove his point.

Earle helped to found the American Psychiatric Association and was active in its affairs over the years, serving as its President in 1884-1885. In the latter year he also resigned his position at Northampton but accepted the state's offer of an apartment there and thus continued his bachelor life at the asylum which he had served for 20 years. He busied himself with his correspondence and his magnum opus, a genealogy of the Earle family, until he died on May 17, 1892, leaving over half of his \$100,000 estate to philanthropic causes.

COMMENT

THE LAND OF INSULIN ADDICTION

Not 1,000 miles from here is a country called Ladekspiel where taking insulin is a crime. In Ladekspiel it is said that there is no such disease as diabetes. Any person who suffers from it really needs nothing more than will-power to control his diet. People who take insulin are considered addicts. The sale or use of insulin is severely penalized.

Some soft-hearted people say that the insulin addict can not help himself and that if he does not take his insulin he will die. Most respectable people however consider this nothing but the whining of man without will-power. Since the insulin addict does not want to die he has to get insulin any way he can. Because it is illegal to sell it, the vendors charge enormous prices. The insulin addict has no lawful way of getting enough money to keep himself in supply. So he will steal and commit other crimes to get money to buy enough insulin to stay alive. When he is caught he is sent to prison both for the stealing and for the addiction which caused it. Thus in Ladekspiel, a high proportion of all insulin addicts are also criminals. This confirms the contention that insulin addiction is just a matter of bad character.

The law recognizes that insulin is medication in schizophrenia and that it is as an appetite stimulant. Accordingly doctors are permitted to prescribe insulin for these conditions. Indeed they may prescribe it for any condition other than diabetes. If a doctor prescribes insulin for diabetes, it is held that he is pandering to an evil habit. The doctor can then be sent to prison.

There are two large medical societies in Ladekspiel. One is the Ladekspiel Organization of Physicians, commonly abbreviated LOP. The smaller organization is the Medical Academy of the Nation commonly abbreviated MAN. In the opinion of LOP, no doctor should prescribe insulin for diabetes. They say that diabetes is an imaginary disease and that a doctor who tries to treat a diabetic for insulin is helping to support the underworld. The MAN on the

other hand, believes this is a medical matter and that it should be determined by medical research whether diabetes exists or is just a matter of will-power. All respectable physicians belong to LOP and are afraid to become involved in the controversy.

To track down insulin addicts and people who sell insulin, special squads have been organized by the police. In one big city, the Captain in charge of this squad has an illustrated lecture showing how people commit crimes and women sometimes sell their bodies in order to get money enough to buy insulin. This lecture is called "The Perils of Insulin Addiction." In another big city the Lieutenant in charge of the squad is urging a new law which would require that all people who are addicted to insulin be put to death at once. It is argued that this evil problem would be solved once and for all because then there would be no further demand for insulin and the illegal business would fall off. Some members of the MAN believe that even if this were done, some children would be born into the next generation who would need insulin to keep alive. Most respectable authorities say that this is nonsense.

There is much argument as to whether people become insulin addicted through weakness of character or through bad companions. There is also controversy as to whether addicts take insulin because it makes them feel good or whether they take it to prevent the ill effects of being without it. It has been reported that when an insulin addict goes without insulin he develops a variety of symptoms and sometimes becomes unconscious. In the opinion of most respectable people, however, this unconsciousness is a mere pretense: an effort to win sympathy and get a shot of insulin. They are not fooled by it.

The forces of virtue and respectability have finally won and the government has created the "Squad for Insulin Management and Policing" affectionately abbreviated SIMP. The SIMP has been sworn to a crusade dedicated to wiping out the insulin

evil. The parliament (which, in Ladekspiel, is called the Diet) has passed a law which imposes savage penalties on anyone who is found to have a hypodermic syringe in his possession or anything which could be used as a hypodermic syringe such as a test tube, an eyedropper, or equipment for developing photographic films. The assumption is that anyone who has a hypodermic syringe in his possession is an insulin addict unless proved otherwise. The

law also provides 5 year minimum sentences for selling insulin, buying insulin, using insulin or making a public statement to the effect that insulin might be necessary for certain people.

It is now expected that as the new law is vigorously enforced, peace and justice will descend upon Ladekspiel and that this evil will finally be controlled.

Henry A. Davidson, M.D.,
Cedar Grove, N. J.

SOCIALISM

Socialism is contrary to human nature.

Socialism is inseparably interwoven with totalitarianism and the abject worship of the State.

No socialist system can be established without a political police.

Socialism is the philosophy of failure, the creed of ignorance and the gospel of envy.

—CHURCHILL

CORRESPONDENCE

RYTHMS, CYCLES AND PERIODS IN HEALTH AND DISEASE

Editor, THE AMERICAN JOURNAL OF PSYCHIATRY :

SIR : I have studied Dr. DuBois' paper with great interest. I believe however that no paper concerned with this matter, is complete without the basic research done by Wilhelm Fliess who devoted a lifetime to the investigation of periodicity in animals, human beings and plants, in health as well as in sickness. The result of his research is called : "Fliessche Periodenrechnung." His publications started with : *Wilhelm Fliess. Der Ablauf des Lebens. Grundlegung zur exacten Biologie*, 1906 followed by : *Vom Leben und vom Tode*, 1916, *Das Jahr im Lebendigen*, 1919. Many authors have continued to expand Fliess' theory of periodicity. I recommend the book by Wilhelm Schlieper, *Der Rhythmus des Lebendigen. Zur Entdeckung von Wilhelm Fliess*, 1909 ; for authors who are well versed in bio-statistics and mathematics there is enjoyable intellectual calisthenics available : *Grundzuege der Fliesschen Periodenrechnung von Richard Pfennig*, 1918.

According to Fliess, life on our planet is bound to a fundamental biological unity of measure : a male period of 23 and a

female period of 28 days which are the "lifetime unities" (*Lebenszeiten der Einheit*) of the male respectively female living substance. Fliess' theory was derived from biological observation, starting with the menstrual cycle, then he found his theory confirmed in his studies of the maturational periods of child development. Birth and death of human beings and animals, studies in botany with observation of budding, blossoming and fading of plants, periodicities in the development and solution of pathological processes in human beings were so often expressed in multiples of 28 and 23 days, that he finally started to interpret also the uneven figures which did not fit his theory by combining the 23 resp. the 28 figure, claiming intuitively that human beings are originally bisexual in their "anlage."

Although Fliess has not solved the problem of periodicity he surely has shown the way. It is impossible in a short letter to give more than a vague idea about the "Fliessche Periodenrechnung."

John Lanzkron, M.D.,
Middletown, N. Y.

REPLY TO THE FOREGOING

Editor, THE AMERICAN JOURNAL OF PSYCHIATRY :

SIR : I am pleased that Dr. Lanzkron has directed the attention of readers of the Journal to the work of Fliess on the subject of periodicity. The studies of the authors to whom Dr. Lanzkron refers, as well as the contributions of other early investigators, could not be included in a review which was limited, as stated, to

"current thinking" about certain periodic activities.

It is hoped that Dr. Lanzkron's remarks will prompt others to comment on the interesting and voluminous literature pertaining to periodicity.

Franklin S. DuBois, M.D.,
Silver Hill Foundation,
New Canaan, Connecticut.

FUNKENSTEIN TEST

Editor, THE AMERICAN JOURNAL OF PSYCHIATRY:

SIR: A clinical note in the July, 1959 issue of the AJP, Drs. Braun & Rettick present "A Study on the Value of the Funkenstein Test as an Indicator of the Effectiveness of Ataractic Drugs." They present their findings with 30 patients, given the mecholyl and epinephrine test described by Funkenstein, who were subsequently placed on chlorpromazine and reserpine.
